Outline

1. Linear σ model
2. Semiclassical particle-field dynamics
   - Thermal quench (box calculation)
   - Expanding hot-matter droplet
3. Conclusions and outlook

Motivation

- exploring the QCD phase diagram in heavy-ion collisions
- identify observables for different phase transitions (cross-over at low vs. 1st order at high μ_B)
- critical endpoint?!?
- problem: rapidly expanding and cooling "fireballs" ⇒ observables?
- "grand canonical fluctuations" of conserved "charges"?!?
- model fluctuations from dynamics rather than imposed by hand (Langevin/Fokker-Planck)
- here: novel kinetic model based on particle-field dualism

Quark-meson linear σ model

- quark-meson linear σ model
- chiral $SU_L(2) \times SU_R(2) \sim SO(4)$ symmetry
- spontaneously broken to $SU_V(2) \sim SO(3)$
- mesons SO(4): σ (scalar) $\vec{\pi}$ (pseudoscalar)
- constituent quarks: $SU_L(2) \times SU_R(2)$

$$\mathscr{L} = \overline{\psi}[\mathrm{i}\not{\partial} - g(\sigma + \mathrm{i}\vec{\pi} \cdot \vec{\tau}\gamma_5)]\psi - \frac{1}{2}(\partial_\mu \sigma \partial^\mu \sigma + \partial_\mu \vec{\pi} \cdot \partial^\mu \vec{\pi}) - U(\sigma, \vec{\pi})$$

- meson potential

$$U(\sigma, \vec{\pi}) = \frac{\lambda^2}{4}(\sigma^2 + \vec{\pi}^2 - v^2)^2 + f_\pi m_\pi^2 \sigma.$$

- explicit breaking of chiral symmetry

Semiclassical particle-field dynamics

- treat σ bosons on the mean-field level + $\sigma \longleftrightarrow \overline{q} q$

$$\Box\sigma + \lambda(\sigma^2 - \nu^2)\sigma - f_\pi m_\pi^2 + g \left\langle \overline{\psi}\psi \right\rangle = \text{“}I(\sigma \longleftrightarrow \overline{q} q)\text{”}$$

- (anti-)quarks via Boltzmann equation

$$\left[\partial_t + \frac{p}{E_q} \cdot \vec{\nabla}_{\vec{x}} - \vec{\nabla}_{\vec{x}} E_\psi(t,\vec{x},\vec{p}) \cdot \vec{\nabla}_{\vec{p}}\right] f_q(t,\vec{x},\vec{p}) = C(\overline{q}q \rightarrow \overline{q}q, \sigma \longleftrightarrow \overline{q}q)$$

$$\text{with} \quad E(t,\vec{x},\vec{p}) = \sqrt{\vec{p}^2 + g^2\sigma^2(t,\vec{x})}$$

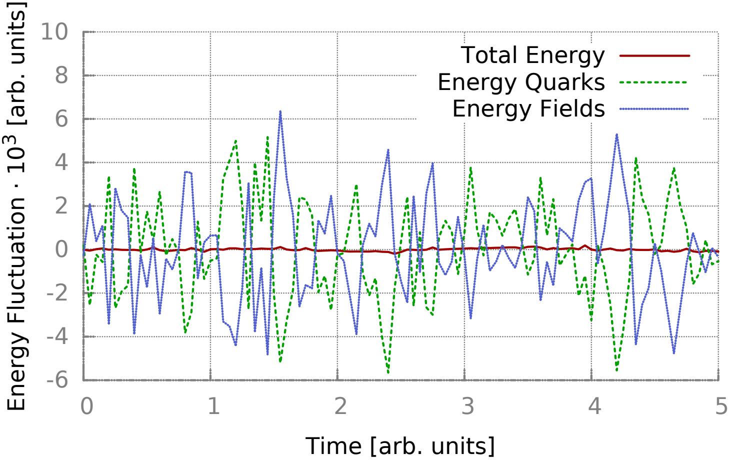
- test-particle ansatz for (anti-)quarks on a spatial grid
- “particle-field dualism” of σ **field** $\longleftrightarrow$ **particle** for “collision terms”

Semiclassical particle-field dynamics

- $\sigma \rightarrow \overline{q} + q$
  - calculate energy and momentum of σ **field** in cell
  - determine local temperature and chemical potential
  - Boltzmann distribution ⇒ σ-**particle** momentum distribution
  - use σ-decay width/rate (matrix element) from QFT in collision terms
- $\overline{q} + q \rightarrow \sigma$
  - "Monte-Carlo" event according to matrix element from σ model
  - add corresponding energy and momentum of σ **particle** as a corresponding Gaussian wave packet to σ **field**
- energy-momentum and baryon-number conservation
- principle of detailed balance fulfilled!

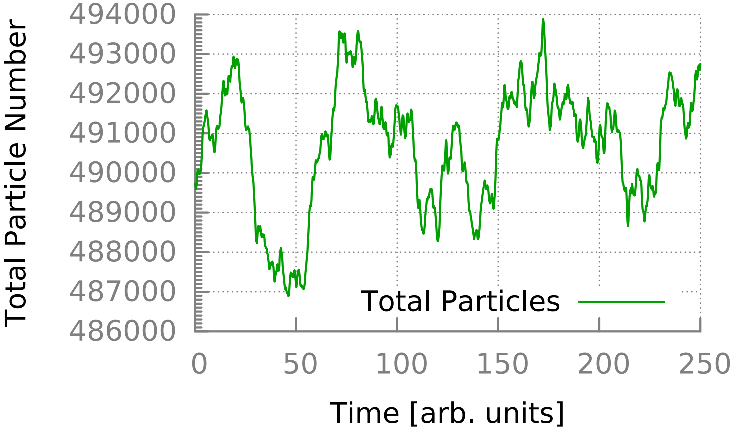
Test: energy conservation (box calculation)

- uncorrelated thermal fluctuations $\Delta E_q / E_q \sim 10^{-3}$ and $\Delta E_\sigma / E \sim 10^{-2}$
- $\Delta E_{\text{tot}} / E_{\text{tot}} \lesssim 5 \cdot 10^{-5}$



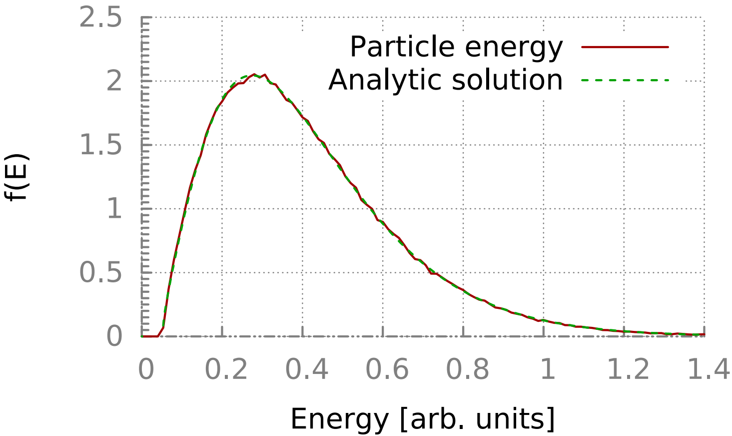
Test: quark-number fluctuations (box calculation)

- total number of (anti-)quarks ($N_q = N_{\overline{q}}$) fluctuates due to $\sigma \longleftrightarrow \overline{q} + q$



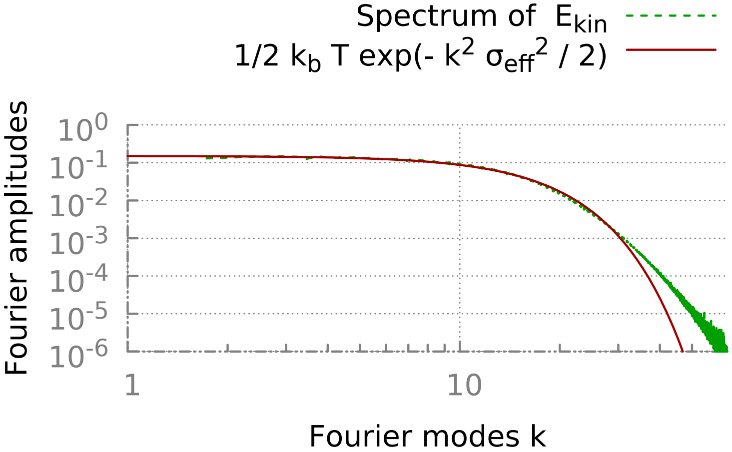
Test: Equilibration limit (box calculation)

- run algorithm in box until q-$\overline{q}$ distribution and σ field stationary
- excellent agreement with relativistic Boltzmann distribution



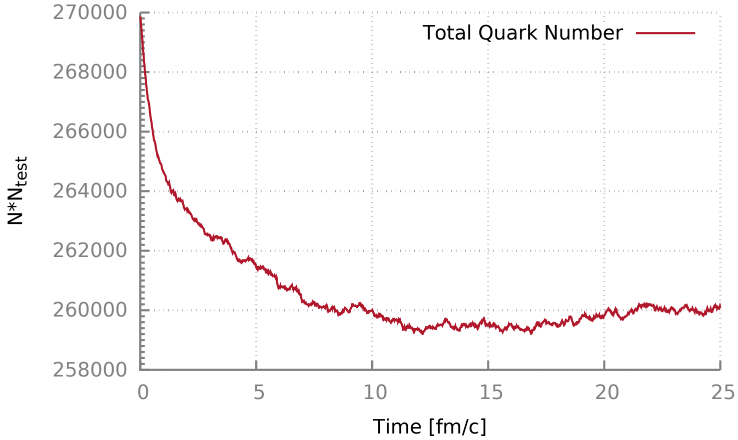
Test: Equilibration limit (box calculation)

- run algorithm in box until q-$\overline{q}$ distribution and σ field stationary
- Fourier spectrum of σ-field energy
- "UV catastrophy" avoided due to finite width σ_{eff} of Gaussian wave packets $\longleftrightarrow$ energy-momentum transfer between particles and fields



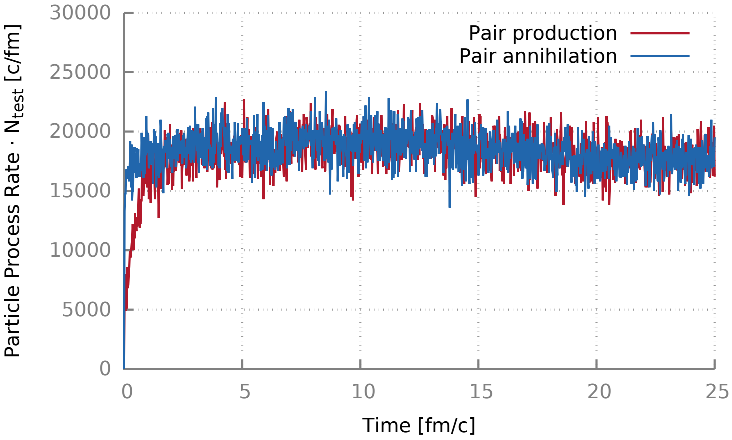
Thermal quench (no phase transition)

- start system with $T_\sigma = 180$ MeV, $T_{\bar{q}q} = 140$ MeV
- system always in chirally restored phase



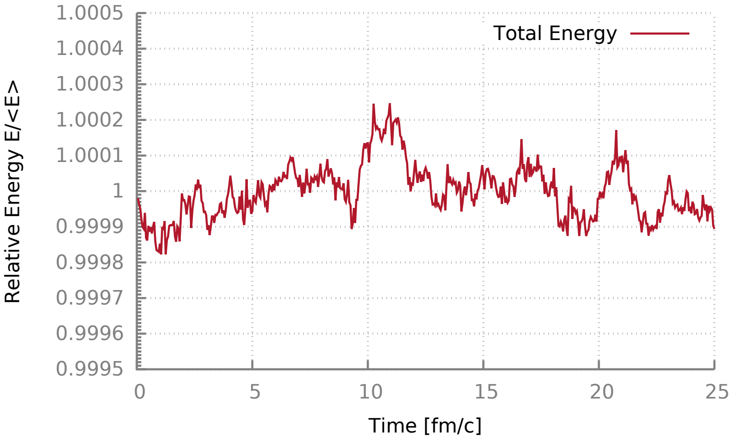
Thermal quench (no phase transition)

- start system with $T_\sigma = 180\,\text{MeV}$, $T_{\bar{q}q} = 140\,\text{MeV}$
- system always in chirally restored phase



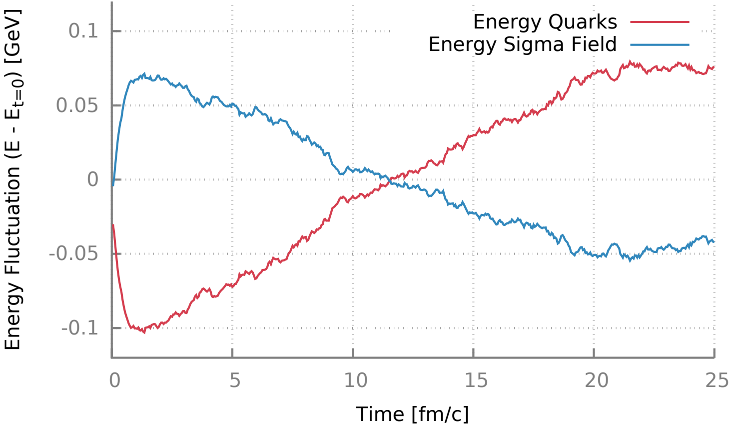
Thermal quench (no phase transition)

- start system with $T_\sigma = 180\,\text{MeV}$, $T_{\bar{q}q} = 140\,\text{MeV}$
- system always in chirally restored phase



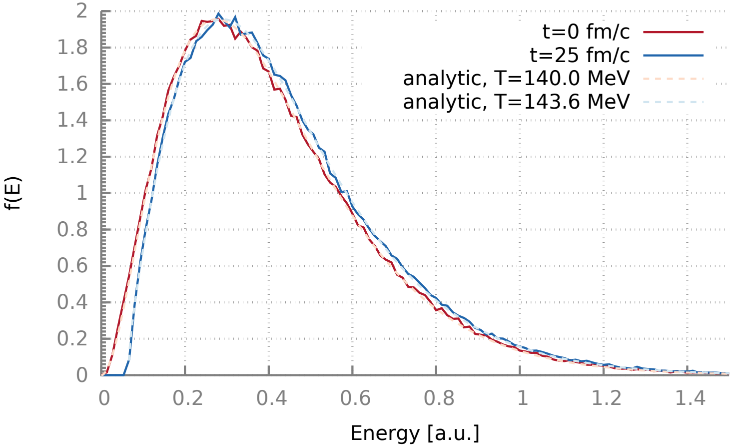
Thermal quench (no phase transition)

- start system with $T_\sigma = 180\,\text{MeV}$, $T_{\bar{q}q} = 140\,\text{MeV}$
- system always in chirally restored phase



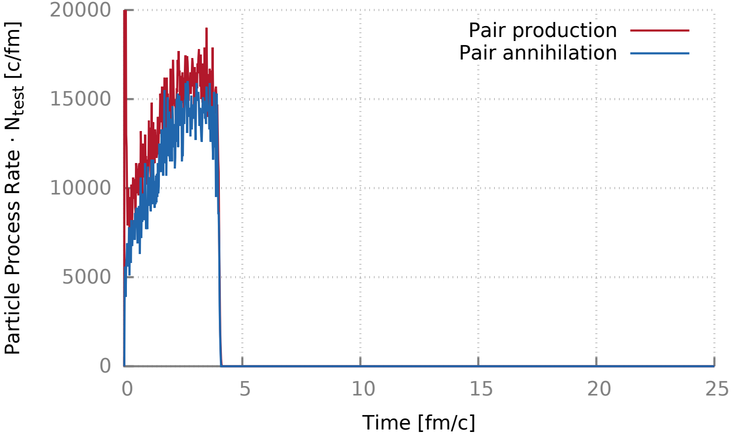
Thermal quench (no phase transition)

- start system with $T_\sigma = 180$ MeV, $T_{\overline{q}q} = 140$ MeV
- system always in chirally restored phase
- system comes to thermal equilibrium ($\sigma \longleftrightarrow \overline{q}q$ always "active")



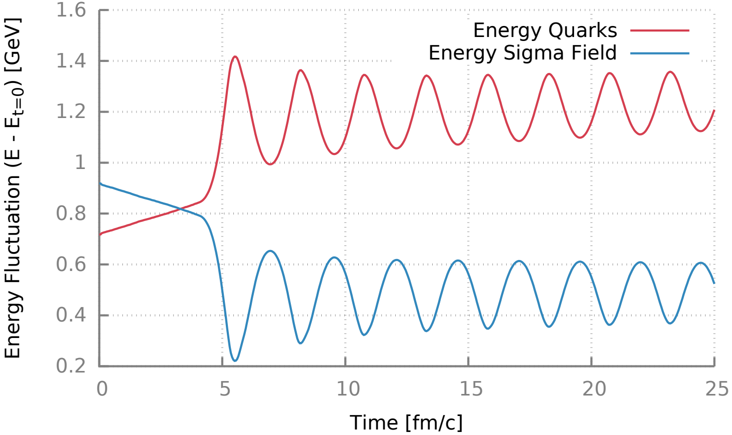
Thermal quench (χ restored $\longrightarrow$ broken phase)

- start system with $T_\sigma = 180\,\text{MeV}$, $T_{\overline{q}q} = 80\,\text{MeV}$
- system undergoes transition from chirally restored to broken phase
- system does not come to thermal equilibrium
  ($\sigma \longleftrightarrow \overline{q}q$ becomes impossible because $m_\sigma < 2m_q$)

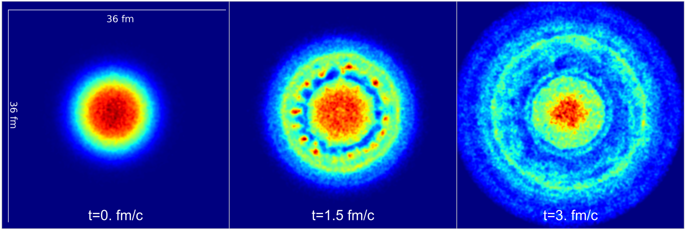


Thermal quench (χ restored $\longrightarrow$ broken phase)

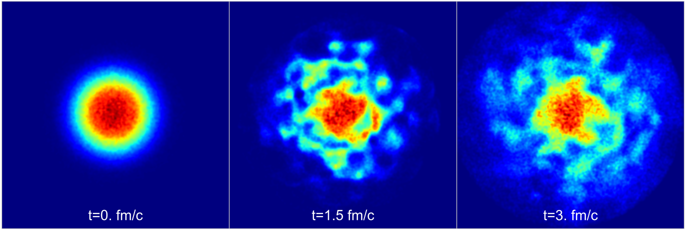
- start system with $T_\sigma = 180$ MeV, $T_{\overline{q}q} = 80$ MeV
- system undergoes transition from chirally restored to broken phase
- ($\sigma \longleftrightarrow \overline{q}q$ becomes impossible because $m_\sigma < 2m_q$)
  after "decoupling" oscillations in σ field $\Leftrightarrow$ $E_{q\overline{q}}$



without "chemical processes"

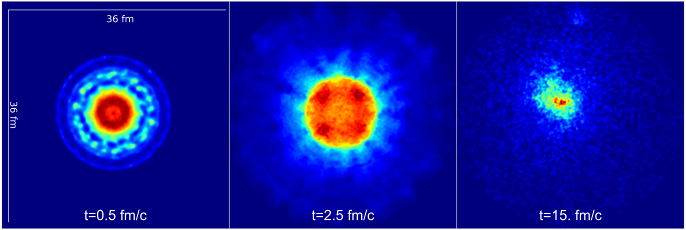


with "chemical processes" ($\sigma \longleftrightarrow \overline{q} + q$)

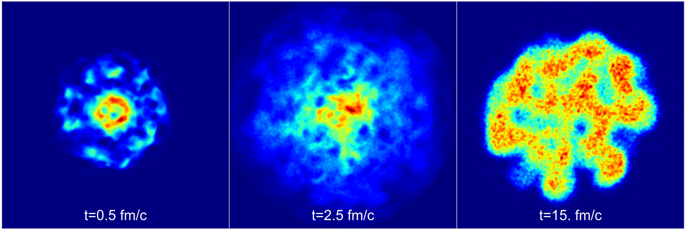


Expanding hot-matter droplet (cross-over at $g = 5.5$)

without "chemical processes"



with "chemical processes" ($\sigma \longleftrightarrow \overline{q} + q$)



Conclusions and outlook

- novel scheme to model off-equilibrium kinetics of phase transitions based on particle-field duality
- application to linear quark-meson σ model
- obeys conservation laws and detailed balance
- dynamically generated fluctuations (no assumptions as in Langevin!)
- passes box-calculation tests
- thermal quench + expanding fireballs
- qualitative difference between cross-over and 1st-order scenario
- to do: how quantifiable?
- possible observables in heavy-ion collisions (e.g., “grand-canonical fluctuations” of baryon number)?
