# Recent Results on Renormalization-Group Evolution of Theories with Gauge, Fermion, and Scalar Fields

Robert Shrock

C. N. Yang Institute for Theoretical Physics, Stony Brook University

Heraeus Workshop on Strong Interactions in the LHC Era, Bad Honnef, Nov. 13, 2014

# Outline

- Renormalization-group flow from UV to IR in asymptotically free gauge theory; types of IR behavior; role of an exact or approximate IR fixed point

- Higher-loop calculations of UV to IR evolution, including IR zero of $\beta$ and anomalous dimension $\gamma_m$ of fermion bilinear

- Some comparisons with lattice measurements of $\gamma_m$

- Higher-loop calculation of structural properties of $\beta$

- Results in the limit $N_c \to \infty$, $N_f \to \infty$ with $N_f/N_c$ fixed

- Study of scheme-dependence

- RG evolution in U(1), $\lambda|\vec{\phi}|^4$, and Yukawa theories

- Conclusions

# RG Flow from UV to IR; Types of IR Behavior and Role of IR Fixed Point

Consider an asymptotically free, vectorial gauge theory with gauge group $G$ and $N_f$ massless fermions in representation $R$ of $G$.

Asymptotic freedom $\Rightarrow$ theory is weakly coupled, properties are perturbatively calculable for large Euclidean momentum scale $\mu$ in deep ultraviolet (UV).

The question of how this theory flows from large $\mu$ in the UV to small $\mu$ in the infrared (IR) is of fundamental field-theoretic interest.

For some fermion contents, the (perturbatively calculated) beta function of the theory may have an exact or approximate IR fixed point (zero of $\beta$).

Denote running gauge coupling at scale $\mu$ as $g = g(\mu)$, and let $\alpha(\mu) = g(\mu)^2/(4\pi)$ and $a(\mu) = g(\mu)^2/(16\pi^2) = \alpha(\mu)/(4\pi)$.

The dependence of $\alpha(\mu)$ on $\mu$ is described by the renormalization group $\beta$ function

$$\beta_\alpha \equiv \frac{d\alpha}{dt} = -2\alpha \sum_{\ell=1}^{\infty} b_\ell\, a^\ell = -2\alpha \sum_{\ell=1}^{\infty} \bar{b}_\ell\, \alpha^\ell \ ,$$

where $dt = d\ln\mu$, $\ell = $ loop order of the coeff. $b_\ell$, and $\bar{b}_\ell = b_\ell/(4\pi)^\ell$.

Coefficients $b_1$ and $b_2$ in $\beta$ are independent of regularization/renormalization scheme, while $b_\ell$ for $\ell \geq 3$ are scheme-dependent.

Asymptotic freedom means $b_1 > 0$, so $\beta < 0$ for small $\alpha(\mu)$, in neighborhood of UV fixed point (UVFP) at $\alpha = 0$.

As the scale $\mu$ decreases from large values, $\alpha(\mu)$ increases. Denote $\alpha_{cr}$ as minimum value for formation of bilinear fermion condensates and resultant spontaneous chiral symmetry breaking (S$\chi$SB).

Two generic possibilities for $\beta$ and resultant UV to IR flow:

- $\beta$ has no IR zero, so as $\mu$ decreases, $\alpha(\mu)$ increases, eventually beyond the perturbatively calculable region. This is the case for QCD.

- $\beta$ has a IR zero, $\alpha_{IR}$, so as $\mu$ decreases, $\alpha \to \alpha_{IR}$. In this class of theories, there are two further generic possibilities: $\alpha_{IR} < \alpha_{cr}$ or $\alpha_{IR} > \alpha_{cr}$.

If $\alpha_{IR} < \alpha_{cr}$, the zero of $\beta$ at $\alpha_{IR}$ is an exact IR fixed point (IRFP) of the renorm. group (RG) as $\mu \to 0$ and $\alpha \to \alpha_{IR}$, $\beta \to \beta(\alpha_{IR}) = 0$, and the theory becomes exactly scale-invariant with nontrivial anomalous dimensions (Caswell, Banks-Zaks).

If $\beta$ has no IR zero, or an IR zero at $\alpha_{IR} > \alpha_{cr}$, then as $\mu$ decreases through a scale $\Lambda$, $\alpha(\mu)$ exceeds $\alpha_{cr}$ and S$\chi$SB occurs, so fermions gain dynamical masses $\sim \Lambda$.

If S$\chi$SB occurs, then in low-energy effective field theory applicable for $\mu < \Lambda$, one integrates these fermions out, and $\beta$ fn. becomes that of a pure gauge theory, with no IR zero. Hence, if $\beta$ has a zero at $\alpha_{IR} > \alpha_{cr}$, this is only an approx. IRFP of RG.

If $\alpha_{IR}$ is only slightly greater than $\alpha_{cr}$, then, as $\alpha(\mu)$ approaches $\alpha_{IR}$, since $\beta = d\alpha/dt \to 0$, $\alpha(\mu)$ varies very slowly as a function of the scale $\mu$, i.e., there is approximately scale-invariant (= dilatation-invariant, walking) behavior.

S$\chi$SB at $\Lambda$ also breaks the approx. dilatation symmetry, might lead to a resultant approx. NGB, the dilaton. This is not massless, since $\beta(\alpha_{cr})$ is nonzero (Yamawaki et al., Appelquist, Wijewardhana.., Holdom, Terning...).

Denote the $n$-loop $\beta$ fn. as $\beta_{n\ell}$ and the IR zero of $\beta_{n\ell}$ as $\alpha_{IR,n\ell}$.

At the $n = 2$ loop level,

$$\alpha_{IR,2\ell} = -\frac{4\pi b_1}{b_2}$$

which is physical for $b_2 < 0$. One-loop coefficient $b_1$ is (Wilczek, Gross, Politzer)

$$b_1 = \frac{1}{3}(11C_A - 4N_f T_f)$$

where $C_A \equiv C_2(G)$ is quadratic Casimir invariant, $T_f \equiv T(R)$ is trace invariant. Focus here on $G = \mathrm{SU}(N_c)$.

Asymp. freedom requires $N_f < N_{f,b1z}$, where

$$N_{f,b1z} = \frac{11C_A}{4T_f}$$

e.g., for $R =$ fundamental rep., $N_f < (11/2)N_c$.

Two-loop coeff. $b_2$ is (with $C_f \equiv C_2(R)$) (Caswell, Jones)

$$b_2 = \frac{1}{3}\left[34C_A^2 - 4(5C_A + 3C_f)N_f T_f\right]$$

For small $N_f$, $b_2 > 0$; $b_2$ decreases as fn. of $N_f$ and vanishes with sign reversal at $N_f = N_{f,b2z}$, where

$$N_{f,b2z} = \frac{34C_A^2}{4T_f(5C_A + 3C_f)}$$

For arbitrary $G$ and $R$, $N_{f,b2z} < N_{f,b1z}$, so there is always an interval in $N_f$ for which $\beta$ has an IR zero, namely

$$I: \quad N_{f,b2z} < N_f < N_{f,b1z}$$

- for SU(2), $I$:     $5.55 < N_f < 11$
- for SU(3), $I$:     $8.05 < N_f < 16.5$
- As $N_c \to \infty$, $I$:     $2.62 N_c < N_f < 5.5 N_c$.

(expressions evaluated for $N_f \in \mathbb{R}$, but it is understood that physical values of $N_f$ are nonnegative integers.)

As $N_f$ decreases from the upper to lower end of interval $I$, $\alpha_{IR}$ increases. Denote

$$N_f = N_{f,cr} \quad \text{at} \quad \alpha_{IR} = \alpha_{cr}$$

Value of $N_{f,cr}$ is of fundamental importance, since it separates the (zero-temp.) chirally symmetric and broken IR phases.

Intensive current lattice studies of SU($N_c$) gauge theories with $N_f$ copies of fermions in various representations $R$; progress toward determining $N_{f,cr}$ for various $N_c$ and $R$.

# Higher-Loop Corrections to UV → IR Evolution of Gauge Theories

Because of this strong-coupling physics, one should calculate the IR zero in $\beta$, $\alpha_{IR}$, and resultant value of $\gamma_m$ evaluated at $\alpha_{IR}$ to higher-loop order (Ryttov and Shrock, PRD83, 056011 (2011) [arXiv:1011.4542] and Pica and Sannino, PRD83, 035013 (2011) [arXiv:1011.5917]; related work by Gardi, Grunberg, Karliner).

Although coeffs. in $\beta$ at $\ell \geq 3$ loop order are scheme-dependent, results give a measure of accuracy of the 2-loop calc. of the IR zero of $\beta$, and similarly with $\gamma_m$ evaluated at this IR zero.

Make use of calculation of $\beta$ and $\gamma_m$ up to 4-loops in $\overline{\rm MS}$ scheme by Vermaseren, Larin, and van Ritbergen.

The value of higher-loop calculations has been amply shown in comparison of QCD predictions with experimental data, e.g., in $\overline{\rm MS}$ scheme.

Values of $\bar{b}_\ell = b_\ell/(4\pi)^\ell$ for $0 \le N_f < N_{f,b1z}$ and illustrative values of $N_c$; for $N_c = 2$, interval $I$, $N_{f,b2z} < N_f < N_{f,b1z}$, is $5.55 < N_f < 11$:

| $N_c$ | $N_f$ | $\bar{b}_1$ | $\bar{b}_2$ | $\bar{b}_3$ | $\bar{b}_4$ |
|---|---|---|---|---|---|
| 2 | 0 | 0.584 | 0.287 | 0.213 | 0.268 |
| 2 | 1 | 0.5305 | 0.235 | 0.154 | 0.191 |
| 2 | 2 | 0.477 | 0.184 | 0.099 | 0.127 |
| 2 | 3 | 0.424 | 0.132 | 0.047 | 0.078 |
| 2 | 4 | 0.371 | 0.080 | $-0.0003$ | 0.044 |
| 2 | 5 | 0.318 | 0.0385 | $-0.044$ | 0.024 |
| 2 | 6 | 0.265 | $-0.023$ | $-0.084$ | 0.020 |
| 2 | 7 | 0.212 | $-0.075$ | $-0.120$ | 0.030 |
| 2 | 8 | 0.159 | $-0.127$ | $-0.152$ | 0.057 |
| 2 | 9 | 0.106 | $-0.178$ | $-0.180$ | 0.099 |
| 2 | 10 | 0.053 | $-0.230$ | $-0.205$ | 0.156 |

For $N_c = 3$, interval $I$, $N_{f,b2z} < N_f < N_{f,b1z}$, is $8.05 < N_f < 16.5$; values of $\bar{b}_\ell$:

| $N_c$ | $N_f$ | $\bar{b}_1$ | $\bar{b}_2$ | $\bar{b}_3$ | $\bar{b}_4$ |
|---|---|---|---|---|---|
| 3 | 0 | 0.875 | 0.646 | 0.720 | 1.173 |
| 3 | 1 | 0.822 | 0.566 | 0.582 | 0.910 |
| 3 | 2 | 0.769 | 0.485 | 0.450 | 0.681 |
| 3 | 3 | 0.716 | 0.405 | 0.324 | 0.485 |
| 3 | 4 | 0.663 | 0.325 | 0.205 | 0.322 |
| 3 | 5 | 0.610 | 0.245 | 0.091 | 0.194 |
| 3 | 6 | 0.557 | 0.165 | $-0.016$ | 0.099 |
| 3 | 7 | 0.504 | 0.084 | $-0.118$ | 0.039 |
| 3 | 8 | 0.451 | 0.004 | $-0.213$ | 0.015 |
| 3 | 9 | 0.398 | $-0.076$ | $-0.303$ | 0.025 |
| 3 | 10 | 0.345 | $-0.156$ | $-0.386$ | 0.072 |
| 3 | 11 | 0.292 | $-0.236$ | $-0.463$ | 0.154 |
| 3 | 12 | 0.239 | $-0.317$ | $-0.534$ | 0.273 |
| 3 | 13 | 0.186 | $-0.397$ | $-0.599$ | 0.429 |
| 3 | 14 | 0.133 | $-0.477$ | $-0.658$ | 0.622 |
| 3 | 15 | 0.080 | $-0.557$ | $-0.711$ | 0.852 |
| 3 | 16 | 0.0265 | $-0.637$ | $-0.758$ | 1.121 |

3-loop coefficient in $\beta$ function (in $\overline{\text{MS}}$ scheme):

$$b_3 = \frac{2857}{54}C_A^3 + T_f N_f \left[ 2C_f^2 - \frac{205}{9}C_A C_f - \frac{1415}{27}C_A^2 \right]$$
$$+ (T_f N_f)^2 \left[ \frac{44}{9}C_f + \frac{158}{27}C_A \right]$$

Here, $b_3 < 0$ for $N_f \in I$. Since $\beta_{3\ell} = -[\alpha^2/(2\pi)](b_1 + b_2 a + b_3 a^2)$, $\beta_{3\ell} = 0$ away from $\alpha = 0$ at two values:

$$\alpha = \frac{2\pi}{b_3}\left( -b_2 \pm \sqrt{b_2^2 - 4b_1 b_3} \right)$$

Since $b_2 < 0$ and $b_3 < 0$, can rewrite as

$$\alpha = \frac{2\pi}{|b_3|}\left( -|b_2| \mp \sqrt{b_2^2 + 4b_1|b_3|} \right)$$

Soln. with $-$ sqrt is negative, hence unphysical; soln. with $+$ sqrt is $\alpha_{IR,3\ell}$.

We showed that with $b_3 < 0$ the value of the IR zero decreases when calculated at the 3-loop level, i.e.,

$$\alpha_{IR,3\ell} < \alpha_{IR,2\ell}$$

This can be seen as follows:

$$\alpha_{IR,2\ell} - \alpha_{IR,3\ell} = \frac{4\pi b_1}{|b_2|} - \frac{2\pi}{|b_3|}\left(-|b_2| + \sqrt{b_2^2 + 4b_1|b_3|}\right)$$

$$= \frac{2\pi}{|b_2 b_3|}\left[2b_1|b_3| + b_2^2 - |b_2|\sqrt{b_2^2 + 4b_1|b_3|}\right]$$

The expression in square brackets is positive if and only if

$$(2b_1|b_3| + b_2^2)^2 - b_2^2(b_2^2 + 4b_1|b_3|) > 0$$

This difference is equal to the positive-definite quantity $4b_1^2 b_3^2$, which proves the inequality.

In RS, Phys. Rev. D 87, 105005 (2013) [arXiv:1301.3209] we have generalized this.

If a scheme had $b_3 > 0$ in $I$, then, since $b_2 \to 0$ at lower end of $I$, $b_2^2 - 4b_1 b_3 < 0$, so this scheme would not have a physical $\alpha_{IR,3\ell}$ in this region.

Since the existence of the IR zero in $\beta$ at 2-loop level is scheme-independent, one may require that a scheme should maintain this property to higher-loop order, and hence that $b_3 < 0$ for $N_f \in I$.

So the inequality $\alpha_{IR,3\ell} < \alpha_{IR,2\ell}$ holds in all such schemes, not just in $\overline{\text{MS}}$.

The 4-loop $\beta$ function is $\beta = -[\alpha^2/(2\pi)](b_1 + b_2 a + b_3 a^2 + b_4 a^3)$, so $\beta_{4\ell}$ has three zeros away from $\alpha = 0$; smallest (real positive) one as $\alpha_{IR,4\ell}$.

We give an analysis of the zeros of $\beta_{4\ell}$ in a general scheme in RS, Phys. Rev. D 87, 105005 (2013) [arXiv:1301.3209]. With $\overline{\text{MS}}$, from 3- to 4-loop level, slight increase: $\alpha_{IR,4\ell} \gtrsim \alpha_{IR,3\ell}$; small change, so overall, $\alpha_{IR,4\ell} < \alpha_{IR,2\ell}$.

Our result of smaller fractional change in value of IR zero of $\beta$ at higher-loop order agrees with expectation that calc. to higher loop order should give more stable result.

Numerical values of $\alpha_{IR,n\ell}$ at the $n = 2, \ 3, \ 4$ loop level for SU(2), SU(3) and fermions in fund. rep., with $n = 3, \ 4$ terms in $\beta$ function in $\overline{\text{MS}}$ scheme:

| $N_c$ | $N_f$ | $\alpha_{IR,2\ell}$ | $\alpha_{IR,3\ell}$ | $\alpha_{IR,4\ell}$ |
|---|---|---|---|---|
| 2 | 6 | 11.42 | 1.645 | 2.395 |
| 2 | 7 | 2.83 | 1.05 | 1.21 |
| 2 | 8 | 1.26 | 0.688 | 0.760 |
| 2 | 9 | 0.595 | 0.418 | 0.444 |
| 2 | 10 | 0.231 | 0.196 | 0.200 |
| 3 | 10 | 2.21 | 0.764 | 0.815 |
| 3 | 11 | 1.23 | 0.578 | 0.626 |
| 3 | 12 | 0.754 | 0.435 | 0.470 |
| 3 | 13 | 0.468 | 0.317 | 0.337 |
| 3 | 14 | 0.278 | 0.215 | 0.224 |
| 3 | 15 | 0.143 | 0.123 | 0.126 |
| 3 | 16 | 0.0416 | 0.0397 | 0.0398 |

(Perturbative calc. not applicable if $\alpha_{IR,n\ell}$ too large.) We have performed the corresponding higher-loop calculations for SU($N_c$) gauge theories with $N_f$ fermions in the adjoint, symmetric and antisymmetric rank-2 tensor representations.

We prove a general result on the shift of an IR zero of $\beta$ when calculated at next higher order: assume fermion content is such that $b_2 < 0$, so theory has a 2-loop IR zero (RS, PRD 87, 105005 (2013) [arXiv:1301.3209]).

Consider a scheme in which the $b_\ell$ with $\ell = 3, ..., n+1$ have values that preserve the existence of the scheme-independent 2-loop IR zero of $\beta$ at higher-loop level (motivated physically).

Use fact that theory is asymptotically free, so $\beta < 0$ for $0 < \alpha < \alpha_{IR}$, and hence $d\beta_{n\ell}/d\alpha > 0$ for $\alpha \simeq \alpha_{IR,n\ell}$.

Expand $\beta_{n\ell}$ in Taylor series around $\alpha = \alpha_{IR,n\ell}$:

$$\beta_{n\ell} = \beta'_{IR,n\ell}\,(\alpha - \alpha_{IR,n\ell}) + O\Big((\alpha - \alpha_{IR,n\ell})^2\Big)$$

Now calculate $\beta$ to the next-higher-loop order, i.e., $\beta_{(n+1)\ell}$, and solve for $\alpha_{IR,(n+1)\ell}$. To determine whether $\alpha_{IR,(n+1)\ell}$ is larger or smaller than $\alpha_{IR,n\ell}$, consider

$$\beta_{(n+1)\ell} - \beta_{n\ell} = -2\bar{b}_{n+1}\alpha^{n+2}$$

In a scheme where $b_{n+1} > 0$, this difference, evaluated at $\alpha = \alpha_{IR,n\ell}$, is negative, so, given that $d\beta_{n\ell}/d\alpha|_{\alpha_{IR,n\ell}} > 0$, to compensate for this, the zero shifts to the right, whereas if $b_{n+1} < 0$, the difference is positive, so the zero shifts to the left.

$$\text{If } b_{n+1} > 0 , \quad \text{then } \alpha_{IR,(n+1)\ell} > \alpha_{IR,n\ell}$$

$$\text{If } b_{n+1} < 0 , \quad \text{then } \alpha_{IR,(n+1)\ell} < \alpha_{IR,n\ell}$$

This general result is evident in our $\overline{MS}$ calculations.

$$b_3 < 0, \quad \Longrightarrow \quad \alpha_{IR,3\ell} < \alpha_{IR,2\ell}$$

$$b_4 > 0, \quad \Longrightarrow \quad \alpha_{IR,4\ell} > \alpha_{IR,3\ell}$$

It is of interest to calculate the anomalous dimension $\gamma_m \equiv \gamma$ for the fermion bilinear, with series expansion

$$\gamma = \sum_{\ell=1}^{\infty} c_\ell a^\ell = \sum_{\ell=1}^{\infty} \bar{c}_\ell \alpha^\ell$$

where $\bar{c}_\ell = c_\ell/(4\pi)^\ell$ is the $\ell$-loop coefficient.

The one-loop coeff. $c_1$ is scheme-independent, the $c_\ell$ with $\ell \geq 2$ are scheme-dependent and have been calculated up to 4-loop level in $\overline{\text{MS}}$ scheme (Vermaseren, Larin, and van Ritbergen): $c_1 = 6C_f$,

$$c_2 = 2C_f \left[ \frac{3}{2}C_f + \frac{97}{6}C_A - \frac{10}{3}T_f N_f \right]$$

$$c_3 = 2C_f \left[ \frac{129}{2}C_f^2 - \frac{129}{4}C_f C_A + \frac{11413}{108}C_A^2 \right.$$
$$+ C_f T_f N_f(-46 + 48\zeta(3)) - C_A T_f N_f(\frac{556}{27} + 48\zeta(3))$$
$$\left. - \frac{140}{27}(T_f N_f)^2 \right]$$

and similarly for $c_4$, where $\zeta(s) = \sum_{n=1}^{\infty} n^{-s}$ and $\zeta(3) = 1.202..$

Denote $\gamma$ calculated to $n$-loop $(n\ell)$ level as $\gamma_{n\ell}$ and, evaluated at the $n$-loop value of the IR zero of $\beta$, as

$$\gamma_{IR,n\ell} \equiv \gamma_{n\ell}(\alpha = \alpha_{IR,n\ell})$$

In the IR chirally symmetric phase, an all-order calculation of $\gamma$ evaluated at an all-order calculation of $\alpha_{IR}$ would be an exact property of the theory.

In the chirally broken phase, just as the IR zero of $\beta$ is only an approx. IRFP, so also, the $\gamma$ is only approx., describing the running of $\bar{\psi}\psi$ and the dynamically generated running fermion mass near the zero of $\beta$ having large-momentum (large $k$) behavior

$$\Sigma(k) \sim \Lambda\left(\frac{\Lambda}{k}\right)^{2-\gamma}$$

where $\gamma$ is bounded above as $\gamma < 2$. Schwinger-Dyson estimates suggest $\gamma$ could be $\sim 1$ in walking regime with S$\chi$SB (Yamawaki et al., Appelquist, Wijewardhana..Lane). The upper bound $\gamma < 2$ also holds for the chirally symmetric conformal IR phase; from a unitarity argument (Mack), $\dim(\bar{\psi}\psi) = 3 - \gamma_m > 1$, so $\gamma < 2$.

At the 2-loop level we calculate

$$\gamma_{IR,2\ell} = \frac{C_f(11C_A - 4T_fN_f)[455C_A^2 + 99C_AC_f + (180C_f - 248C_A)T_fN_f + 80(T_fN_f)^2]}{12[-17C_A^2 + 2(5C_A + 3C_f)T_fN_f]^2}$$

Our analytic expressions for $\gamma_{IR,n\ell}$ at the 3-loop and 4-loop level are more complicated.

Illustrative numerical values of $\gamma_{IR,n\ell}$ for SU(2) and SU(3) at the $n = 2,\ 3, 4$ loop level and fermions in the fundamental representation with $N_f \in I$:

| $N_c$ | $N_f$ | $\gamma_{IR,2\ell}$ | $\gamma_{IR,3\ell}$ | $\gamma_{IR,4\ell}$ |

Plots of $\gamma$ as function of $N_f$ for SU(2) and SU(3):
Figure 1: $n$-loop anomalous dimension $\gamma_{IR,n\ell}$ at $\alpha_{IR,n\ell}$ for SU(2) with $N_f$ fermions in fund. rep. (i) blue: $\gamma_{IR,2\ell}$; (ii) red: $\gamma_{IR,3\ell}$; (iii) brown: $\gamma_{IR,4\ell}$.
Figure 2: $n$-loop anomalous dimension $\gamma_{IR,n\ell}$ at $\alpha_{IR,n\ell}$ for SU(3) with $N_f$ fermions in fund. rep: (i) blue: $\gamma_{IR,2\ell}$; (ii) red: $\gamma_{IR,3\ell}$; (iii) brown: $\gamma_{IR,4\ell}$.

A necessary condition for a perturbative calculation to be reliable is that higher-order contributions do not modify the result too much. We find that the 3-loop and 4-loop results are closer to each other for a larger range of $N_f$ than the 2-loop and 3-loop results.

We have also done higher-loop calcs. for a supersymmetric gauge theory in Ryttov and Shrock, PRD 85, 076009 (2012) [arXiv:1202.1297].

So our higher-loop calcs. of $\alpha_{IR}$ and $\gamma$ allow us to probe the theory reliably down to smaller values of $N_f$ and thus stronger couplings, closer to $N_{f,cr}$. Of course, perturbative calculations are not applicable when $\alpha$ is too large.

We have performed these higher-loop calculations for larger fermion reps. $R$. In general, we find that, for a given $N_c$, $R$, and $N_f$, the values of $\gamma_{IR,n\ell}$ calculated to 3-loop and 4-loop order are smaller than the 2-loop value.

# Comparisons with Lattice Measurements

We compare these calculations with lattice measurements here.

N.B.: for some theories with given gauge group and fermion content, there is not yet a consensus as to whether the theory is chirally symmetric or chirally broken in the IR.

One of the most heavily studied cases on the lattice is for the gauge group SU(3) with $N_f = 12$ fermions in the fundamental representation (with extrapolations to the continuum limit and to massless fermions):

For this theory, Appelquist et al. (LSD); Deuzeman, Lombardo, and Pallante; Hasenfratz et al.; DeGrand et al.; Aoki et al. find that the IR behavior is chirally symmetric, while Jin and Mawhinney and Kuti et al. find that it is chirally broken.

For this SU(3) theory with $N_f = 12$, our calculations give

$$\gamma_{IR,2\ell} = 0.77, \qquad \gamma_{IR,3\ell} = 0.31, \qquad \gamma_{IR,4\ell} = 0.25$$

some lattice results (N.B. - error estimates do not include all systematic uncertainties):

$\gamma = 0.414 \pm 0.016$  (Appelquist et al., PRD 84, 054501 (2011) [arXiv:1106.2148])

$\gamma \sim 0.35$  (DeGrand, PRD 84, 116901 (2011) [arXiv:1109.1237])

$0.2 \lesssim \gamma \lesssim 0.4$  (Kuti et al. (method-dep.) arXiv:1205.1878, arXiv:1211.3548, 1211.6164, PTP, finding S$\chi$SB)

$\gamma = 0.4 - 0.5$  (Y. Aoki et al., (LatKMI) PRD 86, 054506 (2012) [arXiv:1207.3060])

$\gamma = 0.27(3)$  (Hasenfratz et al., arXiv:1207.7162; $\gamma \simeq 0.25$ (Hasenfratz et al., arXiv:1310.1124).

$\gamma = 0.235(46)$  (Lombardo et al., arXiv:1410.0298).

So here the 2-loop value is larger than, and the 3-loop and 4-loop values closer to, these lattice measurements.

Thus, our higher-loop calculations of $\gamma$ yield better agreement with these lattice measurements than two-loop calculations.

SU($N_c$) with fermions in fund. rep. and other $N_f$ values:

SU(3) with $N_f = 10$: Appelquist et al., arXiv:1204.6000 get $\gamma_{IR} \sim 1$

SU(3) with $N_f = 8$, presumably in chirally broken phase; studied by several groups, including LSD group, Appelquist et al., arXiv:1405.4752; LatKMI group, Aoki,... Kurachi et al. PRD 87, 094511 (2013) [arXiv:1302.6859]; get $\gamma_{IR} \sim 1$.

SU(2): $N_f = 6$: Bursa et al., PRD 84, 034506 (2011) [arXiv:1104.4301]; Tuominen et al., JHEP 1205, 003 (2012) [arXiv:1111.4104]; Hayakawa,..Yamada et al., arXiv:1210.4985; PRD88, 094606, 094504, (2013) [arXiv:1307.6696], [arXiv:1307.6997]; T. Appelquist et al., PRL 112, 111601 (2014) (2014) [arXiv:1311.4889]; no consensus yet as to whether this theory has IR chirally symmetric or broken behavior.

Lattice results are consistent with $\gamma_{IR} \sim 1$ in quasi-scale invariant (walking) regime of chirally broken phase. For these theories, the coupling is probably too strong for perturbative methods to be accurate.

SU($N_c$) with fermions in higher-dim. rep.: e.g., for symmetric rank-2 (S2) tensor representation we find

| $N_c$ | $N_f$ | $\gamma_{IR,2\ell,S2}$ | $\gamma_{IR,3\ell,S2}$ | $\gamma_{IR,4\ell,S2}$ |
|---|---|---|---|---|
| 3 | 2 | (2.44) | 1.28 | 1.12 |
| 3 | 3 | 0.144 | 0.133 | 0.133 |
| 4 | 2 | (4.82) | (2.08) | 1.79 |
| 4 | 3 | 0.381 | 0.313 | 0.315 |

Some lattice results for $N_f = 2$ fermions in symmetric rank-2 tensor rep. (no consensus on whether IR theory has spontaneous chiral symmetry breaking or is chirally symmetric, conformal):

e.g., SU(3), $N_f = 2$

$\gamma \lesssim 0.45$ (Degrand, Shamir, Svetitsky, arXiv:1201.0935, PRD88, 054505 (2013) [arXiv:1307.2425], find IR-conformality)

$\gamma \sim 1.5$ (Kuti et al., arXiv:1205.1878, PTP, conclude theory has spontaneous chiral symmetry breaking.)

Also studies by Kogut, Sinclair..

# Further Higher-Loop Structural Properties of $\beta$

In addition to $\alpha_{IR,n\ell}$, further interesting structural properties of the $n$-loop beta fn. $\beta_{n\ell}$ include

- the derivative $\beta'_{IR,n\ell} \equiv \frac{d\beta_{n\ell}}{d\alpha}$ evaluated at $\alpha_{IR,n\ell}$.
- the magnitude and location of the minimum in $\beta_{n\ell}$

In quasi-scale-invariant case where $\alpha_{IR} \gtrsim \alpha_{cr}$, dilaton mass relevant in dynamical EWSB models depends on how small $\beta$ is for $\alpha$ near to $\alpha_{IR}$ and hence, at $n$-loop order, on $\beta'_{IR,n\ell}$, via the series expansion of $\beta_{n\ell}$ around $\alpha_{IR,n\ell}$,

$$\beta_{n\ell}(\alpha) = \beta'_{IR,n\ell} \, (\alpha - \alpha_{IR,n\ell}) + O\Big((\alpha - \alpha_{IR,n\ell})^2\Big)$$

We have calculated these structural properties analytically and numerically in RS, Phys. Rev. D87, 105005 (2013) [arXiv:1301.3209].

Derivative of 2-loop $\beta$ function at $\alpha_{IR,2\ell}$:

$$\beta'_{IR,2\ell} = -\frac{2b_1^2}{b_2} = \frac{2b_1^2}{|b_2|} = \frac{2(11C_A - 4T_f N_f)^2}{3[4(5C_A + 3C_f)T_f N_f - 34C_A^2]}$$

At 3-loop level:

$$\beta'_{IR,3\ell} = \frac{1}{|b_3|^2}\left[ -4|b_2|(b_2^2 + b_1|b_3|) + (b_2^2 + 2b_1|b_3|)\sqrt{b_2^2 + 4b_1|b_3|} \ \right]$$

We prove a general inequality: for a given gauge group $G$, fermion rep. $R$, and $N_f \in I$ (in a scheme with $b_3 < 0$, which thus preserves the existence of the 2-loop IR zero in $\beta$ at 3-loop level),

$$\beta'_{IR,3\ell} < \beta'_{IR,2\ell}$$

We carry out a similar analysis of the derivative of the 4-loop $\beta$ function evaluated at $\alpha_{IR,4\ell}$, denoted $\beta'_{IR,4\ell}$, and find a similar decrease from 3-loop to 4-loop order.

Some numerical values:

| $N_c$ | $N_f$ | $\beta'_{IR,2\ell}$ | $\beta'_{IR,3\ell}$ | $\beta'_{IR,4\ell}$ |
|---|---|---|---|---|
| 2 | 7 | 1.20 | 0.728 | 0.677 |
| 2 | 8 | 0.400 | 0.318 | 0.300 |
| 2 | 9 | 0.126 | 0.115 | 0.110 |
| 2 | 10 | 0.0245 | 0.0239 | 0.0235 |
| 3 | 10 | 1.52 | 0.872 | 0.853 |
| 3 | 11 | 0.720 | 0.517 | 0.498 |
| 3 | 12 | 0.360 | 0.2955 | 0.282 |
| 3 | 13 | 0.174 | 0.156 | 0.149 |
| 3 | 14 | 0.0737 | 0.0699 | 0.0678 |
| 3 | 15 | 0.0227 | 0.0223 | 0.0220 |
| 3 | 16 | 0.00221 | 0.00220 | 0.00220 |

Illustrative figures for SU(2) with $N_f = 8$ fermions and SU(3) with $N_f = 12$ fermions:

Figure 3: $\boldsymbol{\beta_{n\ell}}$ for SU(2), $\boldsymbol{N_f = 8}$, at $\boldsymbol{n = 2,\ 3,\ 4}$ loops. From bottom to top, curves are $\boldsymbol{\beta_{2\ell}}$, $\boldsymbol{\beta_{4\ell}}$, $\boldsymbol{\beta_{3\ell}}$.
Figure 4: $\beta_{n\ell}$ for SU(3), $N_f = 12$, at $n = 2, \ 3, \ 4$ loops. From bottom to top, curves are $\beta_{2\ell}$, $\beta_{4\ell}$, $\beta_{3\ell}$.

Interesting property: for $R =$ fund. rep., $\alpha_{IR,n\ell} N_c$, $\gamma_{IR,n\ell}$, and other structural properties of $\beta_{n\ell}$ are similar in theories with different values of $N_c$ and $N_f$ if they have equal or similar values of $r = N_f/N_c$.

This motivates a study of the UV to IR evolution of an SU($N_c$) gauge theory with $N_f$ fermions in the fundamental rep. in the 't Hooft-Veneziano limit $N_c \to \infty$, $N_f \to \infty$ with $r \equiv N_f/N_c$ fixed and $\alpha(\mu)N_c \equiv \xi(\mu)$ independent of $N_c$. Denote this as the LNN (large $N_c$, large $N_f$) limit.

We have carried out this study in RS, Phys. Rev. D87, 116007 (2013) [arXiv:1302.5434]. Our results provide a unified quantitative understanding of the similarities in UV to IR evolution of SU($N_c$) theories with different $N_c$ and $N_f$ but similar $r$.

With $\xi = \alpha N_c$ and $x = a N_c = \xi/(4\pi)$, define a rescaled beta function that is finite in the LNN limit:

$$\beta_\xi \equiv \frac{d\xi}{dt} = \lim_{LNN} \beta_\alpha N_c$$

with the expansion

$$\beta_\xi \equiv \frac{d\xi}{dt} = -8\pi x \sum_{\ell=1}^{\infty} \hat{b}_\ell x^\ell = -2\xi \sum_{\ell=1}^{\infty} \tilde{b}_\ell \xi^\ell \ ,$$

where

$$\hat{b}_\ell = \lim_{LNN} \frac{b_\ell}{N_c^\ell} \ , \quad \tilde{b}_\ell = \lim_{LNN} \frac{\bar{b}_\ell}{N_c^\ell} \quad \text{so} \ \ \tilde{b}_\ell = \frac{\hat{b}_\ell}{(4\pi)^\ell}$$

1-loop and 2-loop coefficients in $\beta_\xi$:

$$\hat{b}_1 = \frac{1}{3}(11 - 2r)$$

and

$$\hat{b}_2 = \frac{1}{3}(34 - 13r)$$

Asymptotic freedom requires $r < 11/2$. The interval where $\beta_{\xi,2\ell}$ has an IR zero is

$$I_r : \quad \frac{34}{13} < r < \frac{11}{2} \ , \ \ i.e., \quad 2.615 < r < 5.500$$

2-loop IR zero of $\beta_{\xi,2\ell}$ is at

$$\xi_{IR,2\ell} = \frac{4\pi(11 - 2r)}{13r - 34}$$

3-loop and 4-loop coefficients in $\beta_\xi$ (in $\overline{\text{MS}}$ scheme):

$$\hat{b}_3 = \frac{1}{54}(2857 - 1709r + 112r^2) = 52.9074 - 31.6481r + 2.07407r^2$$

$$\hat{b}_4 = \frac{150473}{486} - \left(\frac{485513}{1944}\right)r + \left(\frac{8654}{243}\right)r^2 + \left(\frac{130}{243}\right)r^3 + \frac{4}{9}(11 - 5r + 21r^2)\zeta(3)$$

$$= 315.492 - 252.421\,r + 46.832\,r^2 + 0.534979\,r^3$$

(where $\zeta(s) = \sum_{n=1}^{\infty} n^{-s}$ is Riemann zeta fn.). The 3-loop $\beta$ function $\beta_{\xi,3\ell}$ has an IR zero at

$$\xi_{IR,3\ell} = \frac{12\pi[-3(13r - 34) + \sqrt{C_{3\ell}}\,]}{D_{3\ell}} \, ,$$

where

$$C_{3\ell} = -52450 + 41070r - 7779r^2 + 448r^3$$

$$D_{3\ell} = -2857 + 1709r - 112r^2$$

By same type of proof as given before, we show

$$\xi_{IR,3\ell} \leq \xi_{IR,2\ell}$$

Further, since $\hat{b}_4$ reverses sign from neg. to pos. as $r$ increases through $r = 3.119$,

$$\xi_{IR,4\ell} < \xi_{IR,3\ell} \quad \text{if } 2.615 < r < 3.119, \text{ (where } \hat{b}_4 < 0\text{)},$$

$$\xi_{IR,4\ell} > \xi_{IR,3\ell} \quad \text{if } 3.119 < r < 5.500, \text{ (where } \hat{b}_4 > 0\text{)}$$

Numerical values given in next table. The magnitude of the fractional difference

$$\frac{|\xi_{IR,4\ell} - \xi_{IR,3\ell}|}{\xi_{IR,4\ell}}$$

is reasonably small.

| $r$ | $\xi_{IR,2\ell}$ | $\xi_{IR,3\ell}$ | $\xi_{IR,4\ell}$ |
| --- | --- | --- | --- |
| 2.8 | 28.274 | 3.573 | 3.323 |

| 5.4 | 0.06943 | 0.06769 | 0.06775 |

Value of $n$-loop $\gamma$ evaluated at $n$-loop $\xi_{IR,n\ell}$: $\gamma_{IR,n\ell} \equiv \gamma_{n\ell}\big|_{\xi=\xi_{IR,n\ell}}$;

$$\gamma_{IR,2\ell} = \frac{(11 - 2r)(1009 - 158r + 40r^2)}{12(13r - 34)^2}$$

and so forth for higher-loop order. Numerical values:

| $r$ | $\gamma_{IR,2\ell}$ | $\gamma_{IR,3\ell}$ | $\gamma_{IR,4\ell}$ |
|---|---|---|---|
| 3.6 | 1.853 | 0.5201 | 0.3083 |
| 3.8 | 1.178 | 0.4197 | 0.3061 |
| 4.0 | 0.7847 | 0.3414 | 0.2877 |
| 4.2 | 0.5366 | 0.2771 | 0.2664 |
| 4.4 | 0.3707 | 0.2221 | 0.2173 |
| 4.6 | 0.2543 | 0.1735 | 0.1745 |
| 4.8 | 0.1696 | 0.1294 | 0.1313 |
| 5.0 | 0.1057 | 0.08886 | 0.08999 |
| 5.2 | 0.05620 | 0.05123 | 0.05156 |
| 5.4 | 0.01682 | 0.01637 | 0.01638 |

General inequality as before: $\gamma_{IR,3\ell} < \gamma_{IR,2\ell}$.

We have studied the approach to the LNN limit and find that this is quite rapid, with leading correction terms suppressed by $1/N_c^2$. For example,

$$\alpha_{IR,2\ell} N_c = \frac{4\pi(11-2r)}{13r-34} + \frac{12\pi r(11-2r)}{(34-13r)^2 N_c^2} + O\left(\frac{1}{N_c^4}\right)$$

$$\gamma_{IR,2\ell} = \frac{(11-2r)(1009-158r+40r^2)}{12(13r-34)^2}$$
$$+ \frac{(11-2r)(18836-5331r+648r^2-140r^3)}{(13r-34)^3 N_c^2} + O\left(\frac{1}{N_c^4}\right)$$

(Corresponding study for supersymmetric gauge theory done in Ryttov and RS, op. cit.)

These results provide an understanding of the approximate universality that is exhibited in calculations of these quantities for different (finite) values of $N_c$ and $N_f$ with similar or identical values of $r$.

# Study of Scheme Dependence in Calculation of IR Fixed Point

Since coeffs. $b_n$ in $\beta_{n\ell}$, and hence also $\alpha_{IR,n\ell}$, are scheme-dependent for $n \geq 3$, it is important to assess the effects of this scheme dependence. We have obtained new results in RS, PRD 88, 036003 (2013) [arXiv:1305.6524] and RS, PRD 90, 045011 (2014) [arXiv:1405.6244], extending our earlier studies in Ryttov and RS, PRD 86, 065032 (2012) [arXiv:1206.2366] and PRD 86, 085005 (2012) [arXiv:1206.6895].

A scheme transformation (ST) is a map between $\alpha$ and $\alpha'$ or equivalently, $a$ and $a'$, where $a = \alpha/(4\pi)$ of the form

$$a = a' f(a')$$

with $f(0) = 1$ to keep UV properties unchanged. Write

$$f(a') = 1 + \sum_{s=1}^{s_{max}} k_s (a')^s = 1 + \sum_{s=1}^{s_{max}} \bar{k}_s (\alpha')^s \ ,$$

where $\bar{k}_s = k_s/(4\pi)^s$, and $s_{max}$ may be finite or infinite.

The Jacobian $J = da/da' = d\alpha/d\alpha' = 1 + \sum_{s=1}^{s_{max}} (s+1)k_s(a')^s$, satisfying $J = 1$ at $a = a' = 0$.

After the scheme transformation is applied, the beta function in the new scheme is given by

$$\beta_{\alpha'} \equiv \frac{d\alpha'}{dt} = \frac{d\alpha'}{d\alpha}\frac{d\alpha}{dt} = J^{-1}\beta_\alpha \; .$$

with the expansion

$$\beta_{\alpha'} = -2\alpha' \sum_{\ell=1}^{\infty} b'_\ell (a')^\ell = -2\alpha' \sum_{\ell=1}^{\infty} \bar{b}'_\ell (\alpha')^\ell \; ,$$

where $\bar{b}'_\ell = b'_\ell/(4\pi)^\ell$.

We calculate the $b'_\ell$ as functions of the $b_\ell$ and $k_s$. At 1-loop and 2-loop, this yields the well-known results

$$b'_1 = b_1 \; , \quad b'_2 = b_2$$

We find

$$b'_3 = b_3 + k_1 b_2 + (k_1^2 - k_2)b_1 \; ,$$

$$b'_4 = b_4 + 2k_1 b_3 + k_1^2 b_2 + (-2k_1^3 + 4k_1 k_2 - 2k_3)b_1$$

$$b_5' = b_5 + 3k_1 b_4 + (2k_1^2 + k_2)b_3 + (-k_1^3 + 3k_1 k_2 - k_3)b_2$$
$$+(4k_1^4 - 11k_1^2 k_2 + 6k_1 k_3 + 4k_2^2 - 3k_4)b_1$$

etc. at higher-loop order.

A physically acceptable ST must satisfy several conditions:

- $C_1$: the ST must map a (real positive) $\alpha$ to a real positive $\alpha'$, since a map taking $\alpha > 0$ to $\alpha' = 0$ would be singular, and a map taking $\alpha > 0$ to a negative or complex $\alpha'$ would violate the unitarity of the theory.

- $C_2$: the ST should not map a moderate value of $\alpha$, where perturbation theory is applicable, to a value of $\alpha'$ so large that pert. theory is inapplicable.

- $C_3$: $J$ should not vanish (or diverge) or else there would be a pole in $\beta_{\alpha'}$

- $C_4$: Existence of an IR zero of $\beta$ is a scheme-independent property, so the ST should satisfy the condition that $\beta_\alpha$ has an IR zero if and only if $\beta_{\alpha'}$ has an IR zero.

These conditions can always be satisfied by an ST near the UVFP at $\alpha = \alpha' = 0$, but they are not automatic, and can be quite restrictive at an IRFP.

For example, consider the ST (dependent on a parameter $r$)

$$a = \frac{\tanh(ra')}{r}$$

with inverse

$$a' = \frac{1}{2r} \ln \left( \frac{1 + ra}{1 - ra} \right)$$

(e.g., for $r = 4\pi$, $\alpha = \tanh \alpha'$). This is acceptable for small $a$, but if $a > 1/r$, i.e., $\alpha > 4\pi/r$, it maps a real $\alpha$ to a complex $\alpha'$ and hence is physically unacceptable. For $r = 8\pi$, e.g., this pathology can occur at the moderate value $\alpha = 0.5$.

We have constructed several STs that are acceptable at an IRFP and have studied scheme dependence of the IR zero of $\beta_{n\ell}$ using these. For example,

$$a = \frac{\sinh(ra')}{r}$$

with inverse

$$a' = \frac{1}{r} \ln \left[ ra + \sqrt{1 + (ra)^2} \right]$$

See papers for tables of numerical results for several scheme transformations. Here, we list some numerical results for the $a = (1/r)\sinh(ra')$ scheme transformation with SU(3) and illustrative values of $N_f$ and $r$.

We denote the IR zero of $\beta_{\alpha'}$ at the $n$-loop level as $\alpha'_{IR,n\ell} \equiv \alpha'_{IR,n\ell,r}$.

For $N = 3$, $N_f = 10$, $\alpha_{IR,2\ell} = 2.21$, and:

$$\alpha_{IR,3\ell,\overline{MS}} = 0.764, \quad \alpha'_{IR,3\ell,r=3} = 0.762, \quad \alpha'_{IR,3\ell,r=6} = 0.754,$$

$$\alpha_{IR,4\ell,\overline{MS}} = 0.815, \quad \alpha'_{IR,4\ell,r=3} = 0.812, \quad \alpha'_{IR,4\ell,r=6} = 0.802,$$

For $N = 3$, $N_f = 12$, $\alpha_{IR,2\ell} = 0.754$, and:

$$\alpha_{IR,3\ell,\overline{MS}} = 0.435, \quad \alpha'_{IR,3\ell,r=3} = 0.434, \quad \alpha'_{IR,3\ell,r=6} = 0.433,$$

$$\alpha_{IR,4\ell,\overline{MS}} = 0.470, \quad \alpha'_{IR,4\ell,r=3} = 0.470, \quad \alpha'_{IR,4\ell,r=6} = 0.467,$$

Further studies with other scheme transformations underway; see also T. Ryttov, PRD 89, 016013 (2014) [arXiv:1309.3867]; PRD 89, 056001 (2014) [arXiv:1311.0848]; PRD 90, 056007 (2014) [arXiv:1408.5841].

Our studies provide a quantitative evaluation of scheme-dependent effects in calculations of the IR zero in the beta function. We have constructed scheme transformations that are physically acceptable over the required range of $\alpha_{IR}$ values and have found reasonably small scheme-dependence in the value of the IR zero of $\beta$ for moderate $\alpha_{IR}$.

Our work may be contrasted with studies of scheme/scale dependence in pQCD calculations to optimize convergence of finite-order calcs. (review of recent progress by X.-G. Wu, S. J. Brodsky, and M. Mojaza, Prog. Part. Nucl. Phys. 72, 44 (2013) [arXiv:1302.0599]; see also Garkusha and Kataev, PLB 705, 400 (2011) [arXiv:1108.5909]).

The difference is that the QCD studies apply in the vicinity of the UVFP of QCD at $\alpha = 0$, while our work is for an IR zero away from $\alpha = 0$.

Since the coefficients $b_\ell$ at loop order $\ell \geq 3$ in the beta function are scheme-dependent, one might expect that it would be possible, at least in the vicinity of the UVFP at $\alpha = \alpha' = 0$, to construct a scheme transformations that would set $b'_\ell = 0$ for some range of $\ell \geq 3$, and, indeed a ST that would do this for all $\ell \geq 3$, so that $\beta_{\alpha'}$ would consist only of the 1-loop and 2-loop terms ('t Hooft scheme).

We have constructed an explicit scheme transformation that does this and have studied its range of applicability. Specifically, we construct a scheme transformation, denoted $S_{R,m,k_1}$, that removes the terms in the beta function from loop order 3 up to $m+1$, inclusive. In the limit $m \to \infty$, this transforms to the 't Hooft scheme.

To construct this ST, first, we take advantage of the property that in $b'_\ell$, the ST coefficient $k_{\ell-1}$ appears only linearly. For example, $b'_3 = b_3 + k_1 b_2 + (k_1^2 - k_2)b_1$, etc. for higher-$\ell$ $b'_\ell$.

So solve eq. $b'_3 = 0$ for $k_2$, obtaining

$$k_2 = \frac{b_3}{b_1} + \frac{b_2}{b_1} k_1 + k_1^2$$

This determines $S_{R,2,k_1}$.

To get $S_{R,3,k_1}$, substitute this $k_2$ into expression for $b_4'$ and solve eq. $b_4' = 0$, obtaining

$$k_3 = \frac{b_4}{2b_1} + \frac{3b_3}{b_1} k_1 + \frac{5b_2}{2b_1} k_1^2 + k_1^3$$

This determines $S_{R,3,k_1}$. We continue this procedure iteratively to calculate $S_{R,m,k_1}$ for higher $m$. In general, the equation $b_\ell' = 0$ is a linear equation for $k_{\ell-1}$, so one is guaranteed a unique solution.

So the ST $S_{R,m,k_1}$ has nonzero $k_s$, $s = 1, ..., m$ and in the transformed beta function, sets $b_\ell' = 0$ for $\ell = 3, ..., m+1$. The coefficients $k_s$ for this ST depend on the $b_n$ in the original beta function for $n = 1, ..., m+1$, and on the parameter $k_1$.

We have studied this ST, $S_{R,m,k_1}$ in RS, PRD 90, 045011 (2014) [arXiv:1405.6244] and have shown that it successfully removes the terms of order $\ell$ in beta from $\ell = 3$ up to $\ell = m+1$ inclusive while satisfying the conditions of physical acceptability over reasonably large part of the interval of $N_f \in I$ where the 2-loop beta function has an IR zero.

# Study of RG Flows in Infrared-Free Gauge Theories

If the $\beta$ function of a theory is positive near zero coupling, then this theory is IR-free; as $\mu$ increases from the IR to the UV, the coupling grows. It is of interest to investigate whether an IR-free theory might have a UV fixed point (UV zero of $\beta$).

In addition to performing perturbative calculations of $\beta$ to search for such a UVFP in an IR-free theory, one can use large-$N$ methods. An explicit example is the $O(N)$ nonlinear $\sigma$ model in $d = 2 + \epsilon$ spacetime dimensions. From an exact solution of this model in the limit $N \to \infty$ in 1976, we found that (for small $\epsilon$)

$$\beta(\lambda) = \frac{d\lambda}{dt} = \epsilon\lambda\left(1 - \frac{\lambda}{\lambda_c}\right) , \ \ i.e., \ \ \ \beta(x) = \frac{dx}{dt} = \epsilon x\left(1 - \frac{x}{x_c}\right)$$

where $\lambda$ is the effective coupling, $\lambda_c = 2\pi\epsilon/N$; $x = \lim_{N\to\infty} \lambda N$, $x_c = 2\pi\epsilon$ (W. Bardeen, B. W. Lee, and R. Shrock, Phys. Rev. D 14, 985 (1976); E. Brézin and J. Zinn-Justin, Phys. Rev. B 14, 3110 (1976)). Thus this theory has a UVFP at $x_c$, so that if initial value of $x < x_c$, then $x \nearrow x_c$ as $\mu \to \infty$.

There has long been interest in RG properties of $d = 4$ QED and, more generally, U(1) gauge theory (early work: Gell-Mann and Low; Johnson, Baker, and Willey; Adler; Miransky; Yamawaki,...).

Consider a vectorial U(1) theory with $N_f$ massless Dirac fermions of charge $q$. With no loss of generality, set $q = 1$. Write $\beta$ function as

$$\beta_\alpha = 2\alpha \sum_{\ell=1}^{\infty} b_\ell \, a^\ell$$

The 1-loop and 2-loop coefficients are

$$b_1 = \frac{4N_f}{3} \,, \qquad b_2 = 4N_f$$

These coefficients have the same sign, so the two-loop beta function, $\beta_{\alpha,2\ell}$, does not have a UV zero, and this is the maximal scheme-independent information about it. The coefficients have been calculated up to five loops in the $\overline{\text{MS}}$ scheme.

The 3-loop coefficient (deRafael and Rosner) is negative:

$$b_3 = -2N_f \left( 1 + \frac{22N_f}{9} \right)$$

Hence, $\beta_{\alpha,3\ell}$ has a UV zero, namely,

$$\alpha_{UV,3\ell} = 4\pi a_{UV,3\ell} = \frac{4\pi [9 + \sqrt{3(45 + 44N_f)} \,]}{9 + 22N_f}$$

The 4-loop coefficient is (Gorishny, Kataev, Larin, Surguladze)

$$b_4 = N_f \left[ -46 + \left( \frac{760}{27} - \frac{832\zeta(3)}{9} \right) N_f - \frac{1232}{243} N_f^2 \right]$$

Numerically,

$$b_4 = -N_f \left( 46 + 82.97533 N_f + 5.06996 N_f^2 \right]$$

This is negative for all $N_f > 0$.

Recently, $b_5$ has been calculated (Kataev, Larin; Baikov, Chetyrkin, Kühn, Rittinger, Sturm, 2012, 2013). Numerically,

$$b_5 = N_f(846.6966 + 798.8919 N_f - 148.7919 N_f^2 + 9.22127 N_f^3$$

which is positive for all $N_f > 0$.

In RS, PRD 89, 045019 (2014) [arXiv:1311.5268], we have investigated whether the $n$-loop beta function for this U(1) gauge theory has a UV zero for $n$ up to 5 loops, for a large range of $N_f$. Our results are given in the table (dash means no UV zero).

| $N_f$ | $\alpha_{UV,2\ell}$ | $\alpha_{UV,3\ell}$ | $\alpha_{UV,4\ell}$ | $\alpha_{UV,5\ell}$ |
|---|---|---|---|---|
| 1 | — | 10.2720 | 3.0400 | — |
| 2 | — | 6.8700 | 2.4239 | — |
| 3 | — | 5.3689 | 2.0776 | — |
| 4 | — | 4.5017 | 1.8463 | — |
| 5 | — | 3.9279 | 1.67685 | 2.5570 |
| 10 | — | 2.5871 | 1.2135 | 1.3120 |
| 20 | — | 1.7262 | 0.8483 | — |
| 100 | — | 0.7081 | 0.33265 | — |
| 500 | — | 0.3038 | 0.1203 | — |
| $10^3$ | — | 0.2127 | 0.07678 | — |
| $10^4$ | — | 0.016614 | 0.016965 | — |

A necessary condition for the perturbatively calculated $\beta$ function to yield evidence for a stable UV zero is that it should remain present when one increases the loop order and the fractional change in the value should decrease going from $n$ to $n + 1$ loops.

As is evident from the table, we do not find that the UV zeros that we have calculated at $\ell = 3, \ 4, \ 5$ loop order for a large range of $N_f$ values satisfy this necessary condition. Hence, our results do not give evidence for a UVFP in this theory.

We have also carried out an analysis in the limit

$$N_f \to \infty \quad \text{with finite} \quad y(\mu) \equiv N_f \, a(\mu) = \frac{N_f \, \alpha(\mu)}{4\pi}$$

We denote this as the LNF (large-$N_f$) limit; analogous to $N \to \infty$ limit in nonlinear $\sigma$ model.

We set $b_1 = b_{1,1} N_f$ with $b_{1,1} = 4/3$. Further,

$$b_\ell = \sum_{k=1}^{\ell-1} b_{\ell,k} \, N_f^k \quad \text{for } \ell \geq 2 \, ,$$

where the $b_{\ell,k}$ are independent of $N_f$.

Hence,

$$b_\ell \propto N_f^{\ell-1} \quad \text{for } \ell \geq 2 \quad \text{as } N_f \to \infty$$

We thus define the finite quantities

$$\check{b}_\ell \equiv \frac{b_\ell}{N_f^{\ell-1}} \quad \text{for } \ell \geq 2$$

so

$$\lim_{N_f \to \infty} \check{b}_\ell = b_{\ell,\ell-1} \quad \text{for } \ell \geq 2$$

We define a rescaled $\beta$ function that is finite in the LNF limit as $\beta_y \equiv \beta_\alpha N_f$. Then

$$\beta_y = 8\pi b_{1,1}\, y^2 \left[ 1 + \frac{1}{b_{1,1} N_f} \sum_{\ell=2}^{\infty} b_\ell\, y^{\ell-1} \right]$$

The condition that the $n$-loop $\beta_y$, $\beta_{y,n\ell}$, has a zero at $y \neq 0$ is the equation

$$1 + \frac{1}{b_{1,1} N_f} \sum_{\ell=2}^{n} b_\ell\, y^{\ell-1} = 0 \ .$$

In the LNF limit, of the $n-1$ roots of this equation, the relevant one has the approximate form

$$y_{UV,n\ell} \sim \left( -\frac{b_{1,1} N_f}{b_{n,n-1}} \right)^{\frac{1}{n-1}}$$

Hence, $\beta_{y,n\ell}$ has a zero for $y \neq 0$ in the LNF limit if and only if $b_{n,n-1} < 0$, which is not, in general true. Further, even if it were true for a given loop order $n$, in the LNF limit, $\lim_{N_f \to \infty} y_{UV,n\ell} = \infty$.

One can reexpress $\beta_y$ as a series in powers of $\nu \equiv 1/N_f$:

$$\beta_y = 8\pi b_{1,1}\, y^2 \left[1 + \sum_{s=1}^{\infty} F_s(y)\nu^s\right]$$

An exact integral representation of $F_1(y)$ is known (cf. Holdom, 2010). We have used this representation to determine the signs of $b_{n,n-1}$ up to $n = 24$ loops. We find that these signs are scattered, and show no indication of an onset of negative signs.

Thus, we do not find evidence of a UVFP in a U(1) gauge theory with $N_f$ massless charged fermions for large $N_f$.

We have also studied an SU($N$) non-Abelian gauge theory with $N_f$ massless fermions in a given representation, for large $N_f$. This theory is again IR-free, and we again we do not find evidence of a UVFP.

Gauge theory with fermions and scalar fields can have UVFP: Litim and Sannino, arXiv:1406.2337.

# RG Flows in the $O(N)$ $\lambda|\vec{\phi}|^4$ Theory

We have carried out a similar study, again up to 5-loop order, of another IR-free theory, namely $O(N)$ $\lambda|\vec{\phi}|^4$ theory (in $d = 4$) to search for a possible UV zero of the beta function, in RS, Phys. Rev. D 90, 065023 (2014) [arXiv:1408.3141].

Interaction term: $\mathcal{L}_{int} = -\frac{\lambda}{4!}(\vec{\phi}^2)^2$

$$\beta \text{ function}: \quad \beta_a = \frac{da}{dt} = a\sum_{\ell=1}^{\infty} b_\ell\, a^\ell \quad \text{where} \quad a = \frac{\lambda}{16\pi^2}$$

Coefficients:

$$b_1 = \frac{1}{3}(N + 8), \quad b_2 = -\frac{1}{3}(3N + 14)$$

$$b_3 = \frac{11}{72}N^2 + \left(\frac{461}{108} + \frac{20\zeta(3)}{9}\right)N + \frac{370}{27} + \frac{88\zeta(3)}{9}$$

Numerically,

$$b_3 = 0.15278N^2 + 6.93976N + 24.4571$$

and so forth for $b_4$ and $b_5$ (calculated in $\overline{\text{MS}}$ scheme)

Although the two-loop beta function has a UV zero, it occurs at too large a value of the coupling for the perturbative calculation to be reliable, as shown by the fact that when one calculates to higher-loop order, the 3-loop beta function has no UV zero, and the 4-loop and 5-loop beta functions differ considerably from the 2-loop and 3-loop beta functions where the 2-loop function has a zero.

We have investigated this further via application of scheme transformations and Padé approximants.

We thus conclude that in the range of $\lambda$ where the perturbative calculation of the $n$-loop beta function is reliable, the theory does not exhibit evidence of a UV zero up to the level of $n = 5$ loops.

See figure with beta function curves and table of values of the UV zero $a_{UV,n\ell}$ of the $n$-loop beta function. Dash $-$ means no physical UV zero.
Figure 5: Plot of the $n$-loop $\beta$ function $\beta_{a,n\ell}$ as functions of $a$ for $N = 1$ and (i) $n = 2$ (red), (ii) $n = 3$ (green), (iii) $n = 4$ (blue), and $n = 5$ (black). At $a = 0.18$, going from bottom to top, the curves are for $n = 4$, $n = 2$, $n = 3$, and $n = 5$.

# RG Flows in a Scalar-Fermion Theory

With E. Mølgaard from CP3, SDU, we have calculated RG flows for scalar-fermion theories in Mølgaard and RS, PR D 89, 105007 (2014) [arXiv:1403.3058].
We study two such theories. The first is motivated by the one-generation leptonic sector of the SM with the gauge fields turned off; it has a chiral global symmetry group: $\mathrm{SU}(2)_L \otimes \mathrm{U}(1)_Y$.

fermions: $\psi_L$: fund. rep. of $\mathrm{SU}(2)_L$ with $\mathrm{U}(1)_Y$ charge $Y_\psi$; $\chi_R$: singlet of $\mathrm{SU}(2)_L$ with $\mathrm{U}(1)_Y$ charge $Y_\chi$; scalar $\phi$: fund. rep. of $\mathrm{SU}(2)$ with $\mathrm{U}(1)_Y$ charge $Y_\phi$.

Set $Y_\phi = Y_\psi - Y_\chi$ so Yukawa term $y\bar{\psi}_L \chi_R \phi + h.c.$ allowed.

Fermions in Lagrangian are massless; chiral symmetry forbids fermion masses.

Now the RG flows depend on two couplings rather than one, namely $y$ and the quartic scalar coupling $\lambda$, so they are more complicated than the ones we have discussed so far. Two beta functions (with $dt = d\ln\mu$):

$$\beta_y = \frac{dy}{dt}, \qquad \beta_\lambda = \frac{d\lambda}{dt}$$

Convenient variables:

$$a_y = \frac{y^2}{(4\pi)^2} \,, \qquad a_\lambda = \frac{\lambda}{(4\pi)^2} \,,$$

Corresponding beta functions:

$$\beta_{a_y} = \frac{da_y}{dt} = \frac{2y}{(4\pi)^2} \beta_y \,, \qquad \beta_{a_\lambda} = \frac{da_\lambda}{dt} = \frac{1}{(4\pi)^2} \beta_\lambda \,,$$

As before, a condition for perturbation theory to be reliable is that calculating the beta functions to given loop orders and then comparing with beta functions calculated to one higher loop should give similar results.

With $\beta_y$ and $\beta_\lambda$ calculated to various loop orders (1,1), (1,2), (2,1), (2,2), we have integrated to get the RG flows. See plots of these flows, as functions of $a_y$ and $a_\lambda$:

For small $a_y$ and $a_\lambda$, the RG flow is to the IR-free zero of both beta functions at $a_y = a_\lambda = 0$, i.e., $y = \lambda = 0$.

For larger $y$ and $\lambda$, the flows show further structure.

Figure 6: RG flows obtained via integration of beta functions $\beta_{a_y,\ell}$ and $\beta_{a_\lambda,\ell'}$ for small $a_y$ and $a_\lambda$, calculated for loop orders $(\ell, \ell')$: (1,1) (upper left); (1,2) (upper right); (2,1) (lower left); and (2,2) (lower right). Arrows are flows from UV to IR.
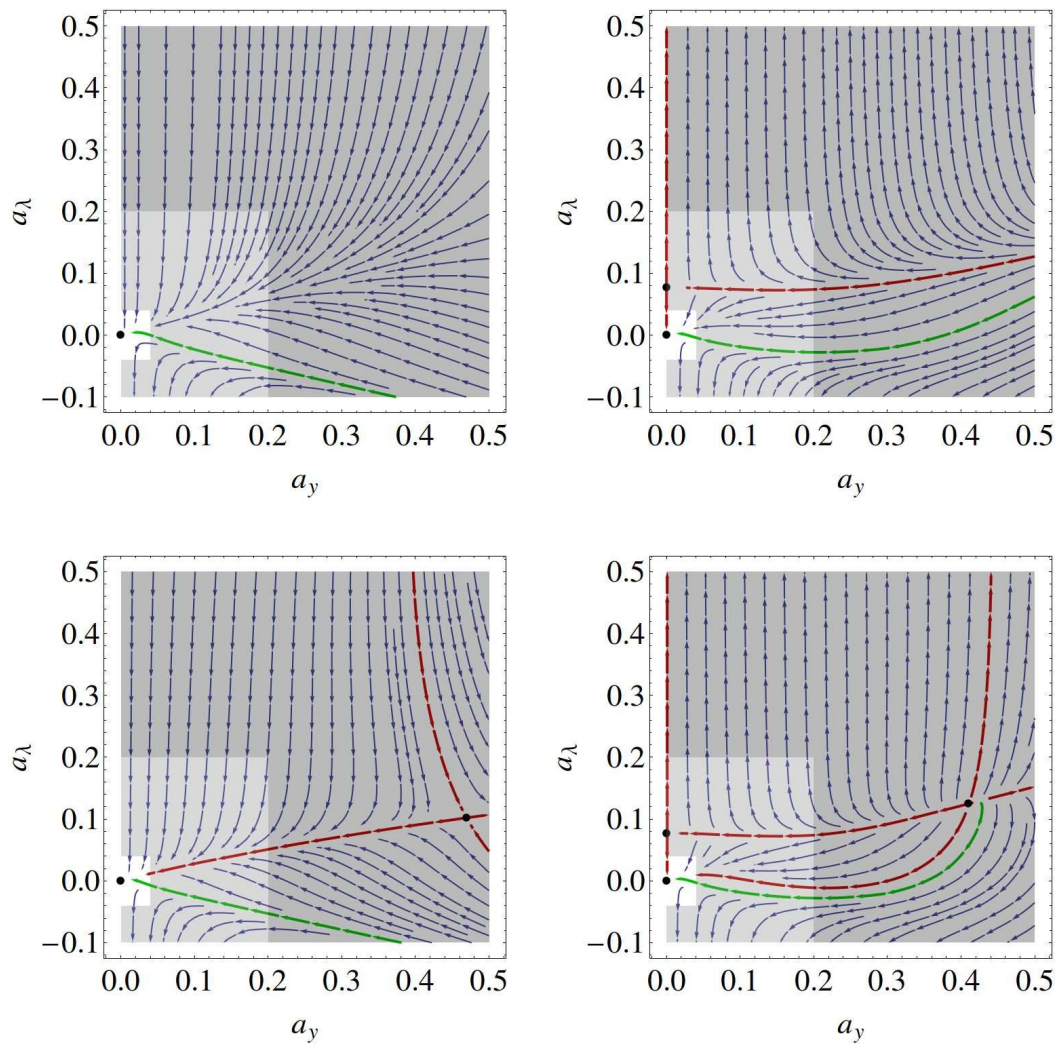

Figure 7: RG flows obtained via integration of beta functions $\boldsymbol{\beta_{a_y,\ell}}$ and $\boldsymbol{\beta_{a_\lambda,\ell'}}$ for moderate $\boldsymbol{a_y}$ and $\boldsymbol{a_\lambda}$, calculated for loop orders $(\boldsymbol{\ell, \ell'})$: (1,1) (upper left); (1,2) (upper right); (2,1) (lower left); and (2,2) (lower right). Arrows are flows from UV to IR.

Comparison of these different loop-order calculations of RG flows yields information on the extent of the region in $a_y$ and $a_\lambda$ where the perturbative calculations agree with each other and hence may be reliable.

Our Mølgaard-RS paper also includes calculations of RG flows for a Yukawa theory with a global symmetry group $\mathrm{SU}(N) \otimes \mathrm{SU}(N_f) \otimes \mathrm{U}(1)$, where the $\mathrm{SU}(N)$ generalizes SU(2) and we include $N_f$ copies (flavors) of fermions. See paper for details. Related work by Sannino et al.

# Conclusions

- Understanding the UV to IR evolution of an asymptotically free gauge theory and the nature of the IR behavior is of fundamental field-theoretic interest.

- Our higher-loop calculations give information on this UV to IR flow and on determination of $\alpha_{IR,n\ell}$ and $\gamma_{IR,n\ell}$.

- Valuable to compare results from higher-loop continuum calcs. with lattice measurements.

- Results on the limit $N_c \to \infty$, $N_f \to \infty$ with $N_f/N_c$ fixed provide insight into the similarities in UV to IR flows in theories with different $N_c$ and $N_f$ but similar $r$.

- We have investigated effects of scheme-dependence of IR zero in the beta function in higher-loop calculations and have constructed explicit scheme transformations that remove higher-loop terms in beta.

- We have studied RG flows in IR-free theories: U(1) gauge theory, nonabelian g.t. with large $N_f$, and $\lambda|\vec{\phi}|^4$, finding evidence against a UV zero in beta fns.

- Also interesting to study RG flows in Yukawa models.
