

GLUON CONDENSATES AS SUSCEPTIBILITY RELATIONS

CP³ Origins
Cosmology & Particle Physics

Roman Zwicky
Edinburgh University

14 Nov 2014 — Strong Dynamics in the LHCera — Bad Honnef

Main result

to be derived and
discussed throughout

$$\bar{g} \frac{\partial}{\partial \bar{g}} M_H^2 = - \frac{1}{2} \langle H(E_H) | \frac{1}{\bar{g}^2} \bar{G}^2 | H(E_H) \rangle_c$$

$$\bar{g} \frac{\partial}{\partial \bar{g}} \Lambda_{\text{GT}} = - \frac{1}{2} \langle 0 | \frac{1}{\bar{g}^2} \bar{G}^2 | 0 \rangle$$

*

Del Debbio and RZ 1306.4274 (PLB'2014)

- advocate: LHS provides a definition of the RHS
- **direct** computation of gluon condensates (RHS) plagued by power divergences — no definite result known
 $\langle 0 | G^2 | 0 \rangle = 0 \pm 0.012 \text{GeV}^4$ c.f. also Ioffe'05 **indirect** determinations

* barred quantities correspond to renormalised quantities & c stands for connected part

N.B. $\frac{\partial}{\partial g} E_H = \frac{\partial}{\partial g} M_H$ $\langle 0 | T_\mu^\mu | 0 \rangle = D \Lambda_{\text{GT}}$

Overview

- Derivations (A) Feynman-Hellmann & Trace anomaly & RG-Eqs
(B) Hamiltonian formalism (direct use of FH-thm)
- Illustration in exactly solvable models
- How to implement coupling derivative
- Where it came from: corrections to scaling of the mass(-operator)
- Epilogue (applications)
- Backup slides: - comment energy momentum tensor on lattice
- issue of Konishi-anomaly

two derivations

(A) trace anomaly, Feynman-Hellmann-thm & RGE

Del Debbio and RZ 1306.4274 (PLB'2014)

Feynman-Hellmann thm: $\frac{\partial E_\lambda}{\partial \lambda} = \langle \psi(\lambda) | \frac{\partial \hat{H}(\lambda)}{\partial \lambda} | \psi(\lambda) \rangle$ idea: $\frac{\partial \langle \psi(\lambda) | \psi(\lambda) \rangle}{\partial \lambda} = 0$

- **useful** provided **H(λ) known** (QFT different normalisation has to be taken into account)

example $H(m) = m N_F \bar{q} q + \dots$

$$\frac{\partial}{\partial \bar{m}} M_\Psi^2 = N_F \langle \psi | \bar{q} q | \psi \rangle_c$$

- For $\lambda=g$ (gauge coupling) complicated since A_0 not dynamical.
Show: if use all ingredients in the title then we can get relations!

- Fix notation $|H(\text{adron})\rangle$: $\langle H(E', \vec{p}') | H(E, \vec{p}) \rangle = 2E(\vec{p}) (2\pi)^{D-1} \delta^{(D-1)}(\vec{p} - \vec{p}')$,

$$\langle X \rangle_{E_H} \equiv \langle H(E, \vec{p}) | X | H(E, \vec{p}) \rangle_c ,$$

$$Q \equiv N_f m \bar{q} q , \quad G \equiv g^{-2} G_{\alpha\beta}^A G^{A\alpha\beta} ,$$

three step procedure

1. EM-tensor & trace anomaly :

$$T_{\mu}^{\mu}|_{\text{on-shell}} = \frac{\bar{\beta}}{2\bar{g}} \bar{G} + (1 + \bar{\gamma}_m) \bar{Q} ,$$

Adler et al, Collins et al
N.Nielsen '77 Fujikawa '81

for gauge theory
(bar renormalised quantities
important!)

Evaluate on physical state $|H\rangle$ one gets:

$$2M_H^2 = \frac{\bar{\beta}}{2\bar{g}} \bar{G}_{E_H} + (1 + \bar{\gamma}_m) \bar{Q}_{E_H} , \quad D\Lambda_{\text{GT}} = \frac{\bar{\beta}}{2\bar{g}} \langle \bar{G} \rangle_0 + (1 + \bar{\gamma}_m) \langle \bar{Q} \rangle_0 .$$

trace anomaly (1)

2. Feynman-Hellmann-thm (mass)

$$\bar{m} \frac{\partial}{\partial \bar{m}} E_H^2 = \langle \bar{Q} \rangle_{E_H} , \quad \bar{m} \frac{\partial}{\partial \bar{m}} (D\Lambda_{\text{GT}}) = \langle \bar{Q} \rangle_0 .$$

FH-thm (2)

3. Renormalization group equation

$$\left(\bar{\beta} \frac{\partial}{\partial \bar{g}} - (1 + \bar{\gamma}_m) \bar{m} \frac{\partial}{\partial \bar{m}} + 2 \right) M_H^2 = 0 , \quad \left(\bar{\beta} \frac{\partial}{\partial \bar{g}} - (1 + \bar{\gamma}_m) \bar{m} \frac{\partial}{\partial \bar{m}} + D \right) \Lambda_{\text{GT}} = 0 ,$$

RG (3)

Combining our results takes on the form:

$$\bar{g} \frac{\partial}{\partial \bar{g}} E_H^2 = -\frac{1}{2} \langle \bar{G} \rangle_{E_H} , \quad \bar{g} \frac{\partial}{\partial \bar{g}} \Lambda_{\text{GT}} = -\frac{1}{2} \langle \bar{G} \rangle_0 .$$

(B) After all from the Hamiltonian formalism

Prochazka and RZ JPA 2014
1312.5495

- guiding question: H-formalism is non-covariant! how Lorentz invariance emerge?
 $\vec{\pi} = \vec{E}$, \vec{A} indep. canonical variables ($\pi_0 = 0$, A_0 Lagrangian multiplier)

$$[A^k(x_0, \vec{x}), E_l(x_0, \vec{y})] = i\delta_l^k \delta^{(D-1)}(\vec{x} - \vec{y})$$

$$\mathcal{H} = \mathcal{H}_g + \mathcal{H}_C + \mathcal{H}_G$$

$$\frac{1}{2}(\vec{E}^2 + \vec{B}^2) - \bar{q}(i\vec{\gamma} \cdot (\vec{\partial} + ig\vec{A}) - m)q$$

primary, secondary constraints

$$\text{Gauss constraint } A_0^a ((\vec{D} \cdot \vec{E})^a + \bar{q}t^a \gamma_0 q)$$

$$2B_k = \epsilon_{kij} G_{ij} = \epsilon_{kij} (\partial_i A_j - \partial_j A_i + ig[A_i, A_j])$$

- step 1: only \mathcal{H}_g non-vanishing on physical states - drop $\mathcal{H}_{C,G}$

- step 2: put g 's into right place by

performing canonical transformation: $\vec{A} \rightarrow \frac{1}{g}\vec{A}$, $\vec{E} \rightarrow g\vec{E}$

- a) leaves can. commutator invariant
- b) no rescaling (Konishi) anomaly (non-trivial)

$$\mathcal{H}_g = \frac{1}{2}(g^2 \vec{E}^2 + \frac{1}{g^2} \vec{B}^2) - \bar{q}(i\vec{\gamma} \cdot \vec{\partial} + i\vec{A} + m)q$$

- the pathway to a Lorentz-invariant result is now straightforward ...

$$g \frac{\partial}{\partial g} \mathcal{H}_g = g^2 \vec{E}^2 - \frac{1}{g^2} \vec{B}^2 = -\frac{1}{2} \frac{1}{g^2} G_{\mu\nu} G^{\mu\nu}$$

- very same relations (as before) emerge

$$\bar{g} \frac{\partial}{\partial \bar{g}} E_H^2 = -\frac{1}{2} \langle \bar{G} \rangle_{E_H} , \quad \bar{g} \frac{\partial}{\partial \bar{g}} \Lambda_{\text{GT}} = -\frac{1}{2} \langle \bar{G} \rangle_0 .$$

- **advantage:** the Hamiltonian derivation makes it clear that relation valid for product groups e.g. $G = U(1) \times SU(2) \times SU(3)$

illustration in exactly solvable models

- Schwinger model (QED2 massless fermions) photon mass e^2/π
- massive flavoured Schwinger model cosmological constant
- N=2 SYM (Seiberg-Witten) monopole mass

Photon mass Schwinger model

- Schwinger model: QED2 $m_f=0$ - generation of photon mass: $M_\gamma=e/\sqrt{\pi}$

$$e \frac{\partial}{\partial e} M_\gamma^2 = -\frac{1}{2} \langle \gamma | F^2 | \gamma \rangle_c$$

adaption 2D [e]=1

- Lowenstein-Swieca operator solution can compute RHS —

$$F_{\mu\nu} = \frac{\sqrt{\pi}}{e} \epsilon_{\mu\nu} \square \Sigma$$

Σ free field mass e^2/π

$$\langle \gamma | F^2 | \gamma \rangle_c = \frac{\pi}{e^2} \epsilon_{\mu\nu} \epsilon^{\mu\nu} 2(-M_\gamma^2)^2 = -4 \frac{e^2}{\pi}$$

evaluate on photon state

- Insert into equation above and solve

$$e \frac{\partial}{\partial e} M_\gamma^2 = 2 \frac{e^2}{\pi} \Rightarrow M_\gamma^2 = \frac{e^2}{\pi} + C$$

boundary condition $C=0$ and this completes the illustration!

n=2 SYM (Seiberg-Witten)

- BPS states obey: $\mathbf{M}_{(e,m)} = 2 |n_e \mathbf{a} + n_m \mathbf{a}_D|^2$ where \mathbf{a}, \mathbf{a}_D part of SW-solution
- BPS-Hamiltonian magnetic monopoles ($n_e=0$, \vec{B} static $\Rightarrow \vec{E}=0$ & no fermions as BPS)

$$\mathcal{H}_{\text{BPS}} = \frac{1}{g^2} \vec{D}\phi \cdot \vec{D}\phi + \frac{1}{2} \frac{1}{g^2} \vec{B}^2$$

- BPS-eqn: $\vec{D}\phi | \text{BPS} \rangle = \frac{1}{\sqrt{2}} \vec{B} | \text{BPS} \rangle \Rightarrow \mathcal{H}_{\text{BPS}} = \frac{1}{g^2} \vec{B}^2$

$$g \frac{\partial}{\partial g} \mathcal{H}_{\text{BPS}} = -2 \frac{1}{g^2} \vec{B}^2 \stackrel{\vec{E}=0}{=} -\frac{1}{g^2} G^2$$

*N.B. additional factor 2
because of supersymmetry*

\Rightarrow shown main Eqn obeyed BPS-subspace

- Unlike Schwinger model, can't compute RHS directly
used LHS to get $\text{RHS} = \langle \text{BPS} | G^2 | \text{BPS} \rangle$
RHS governed by magnetic coupling g_D e.g. $\text{RHS} \rightarrow 0$ for $g_D \rightarrow 0$

Implementation of derivative coupling

Implementation of $\frac{\partial M_H}{\partial g}$

- “... is not so immediate in a theory with running coupling” (depends on your background)
- lattice: every QCD parameter $g, m_u, m_d \dots$ is associated with hadronic observable

- step 1: $M_\rho = 770\text{MeV}$ measure coupling in scheme A :

$$g_A(\alpha M_\rho) = c, \quad c, \alpha \in \mathbf{R}$$

- step 2: $M_\rho^\epsilon = 770(1 + \epsilon)\text{MeV}$ measure coupling in scheme A :

$$g_A^\epsilon(\alpha M_\rho) = c_\epsilon \quad (= g_A^\epsilon(\alpha_\epsilon M_\rho^\epsilon), \text{ where } \alpha_\epsilon = \frac{\alpha}{1+\epsilon})^*$$

- finally:

$$\frac{\partial M_\rho}{\partial g_A} = \lim_{\epsilon \rightarrow 0} \frac{M_\rho^\epsilon - M_\rho}{g_A^\epsilon - g_A}$$

* $g_A(x) = g_A^\epsilon(x(1 + \epsilon))$

Where it all came from

scaling correction to hadronic mass in near conformal phase

Del Debbio and RZ 1306.4038 (PRD'2013)

- consider conformal theory with mass deformation expand around fixed pt coupling g^*

$$\beta = \beta_1 \delta g + \mathcal{O}(\delta g^2), \quad \delta g \equiv g - g^*$$

$$\gamma_m = \gamma_m^* + \gamma_m^{(1)} \delta g + \mathcal{O}(\delta g^2),$$

$$\gamma_{ij} = \gamma_{ij}^* + \gamma_{ij}^{(1)} \delta g + \mathcal{O}(\delta g^2), \quad (\gamma_{ij} \equiv (\gamma_O)_{ij}).$$

- each local operator O investigate Callan-Symanzik-Weinberg-'tHooft type RGE

$$\left(\Lambda \frac{\partial}{\partial \Lambda} \delta_{ij} + \beta(g) \frac{\partial}{\partial g} \delta_{ij} - \gamma_m m \frac{\partial}{\partial m} \delta_{ij} - \gamma_{ij} \right) O_j(g, m, \Lambda) = 0$$

UV-cut off: Λ , $\gamma_m = -\Lambda \frac{d}{d\Lambda} \ln m \dots$

- correction to scaling to hadronic mass through
 - RGE above applied to $O = M_H$
 - or apply scaling to all four quantities in trace anomaly

$$2M_H^2 = \left(\frac{\bar{\beta}}{2\bar{g}} \right) \bar{G}_{M_H} + (1 + \bar{\gamma}_m) \bar{Q}_{M_H},$$

a) and b) agree only if **susceptibility relation** hold

Epilogue

$$\bar{g} \frac{\partial}{\partial \bar{g}} E_H^2 = -\frac{1}{2} \langle \bar{G} \rangle_{E_H} , \quad \bar{g} \frac{\partial}{\partial \bar{g}} \Lambda_{\text{GT}} = -\frac{1}{2} \langle \bar{G} \rangle_0 .$$

- Scheme dep. of RHS inherited from scheme dependence of coupling g
- LHS defines RHS - suggest total change of viewpoint
(Recall: direct computation of G -condensate fails because power divergences mixing with lower dimensional operators e.g. identity (quartic UV-divergence))
- Practice computation of **$\langle H | G^2 | H \rangle$** (should be) straightforward
 - a) lattice
 - b) approaches like AdS/QCD or Dyson-Schwinger Eqn which produce M_H
- opens up opportunities to define β and γ_m through interplay with trace anomaly:

$$2M_H^2 = \frac{\bar{\beta}}{2\bar{g}} \langle H | \bar{G}^2 | H \rangle + (1 + \bar{\gamma}_m) \bar{m} \langle H | qq | H \rangle$$

For example if $\bar{m}=0$ then

$$(\bar{\beta}_{\text{YM}})^{-1} = -\frac{\partial}{\partial \bar{g}} \ln M_H$$

- Computation of $\langle 0|G^2|0\rangle$ is more difficult per se
 - on lattice demands mastering EMT problems due to breaking of translation symmetry (additional renormalisation)
 - recent progress using Wilson flow del Debbio, Patella, Rago JHEP(2014)
- check PCD(dilaton)C hypothesis for gauge theory dilation candidate (Higgs imposter) (analogue PCAC soft pion reduction)

$$2m_D^2 = \frac{\beta}{2g} \langle D|G^2|D\rangle + O(m_q) \stackrel{\text{soft dilaton}}{\simeq} \frac{\beta}{2g} \frac{1}{f_D^2} \langle 0|G^2|0\rangle + O(m_q) \quad \langle D|G^2|0\rangle = f_D$$

- compute QCD contribution to cosmological constant
 - N.B. practice mastering EMT already enough -
 - yet relations useful in eliminating constant which is independent of g
- one could do conversion calculation to MS-bar and compare with value extracted from OPE (e.g. charmonium sum rules or SVZ sum rules)

THANKS FOR YOUR ATTENTION

backup slides

renormalisation of energy momentum tensor (EMT)

- **continuum EMT** does **not renormalise** ($Z_{T_{\alpha\beta}} = 1$) since **conserved quantity** (still need to renormalise parameters of theory of course)
- **lattice** break Lorentz symmetry to hyper cubic symmetry hence the EMT is not conserved anymore $Z_{T_{\alpha\beta}} = 1$ does not apply or in other words we can write down further invariant with which the EMT mixes

Problem: how to **tune counterterms**

translation Ward identity to probe EMT

Caracciolo, Curci, Menotti, Pelissetto'90

$$\langle 0 | \int d^3x T_{0\mu}(x) \phi(x_1) \dots \phi(x_n) | 0 \rangle = - \sum_{i=1}^n \frac{\partial}{\partial (x_i)^\mu} \langle 0 | \phi(x_1) \dots \phi(x_n) | 0 \rangle$$

Problem: each probe contact term no gain

- using **Wilson flow** can avoid contact terms (probes are in bulk....)

del Debbio, Patella, Rago JHEP(2014)

issue of konishi anomaly

- rescale field coupled to a gauge field by a constant then term appears G^2 like chiral transformation gives rise to G^*G -term (supersymmetry same footing)

- perform transformation
$$\begin{aligned}\vec{A} &\rightarrow \frac{1}{f(g)}\vec{A}, \\ \vec{E} &\rightarrow f(g)\vec{E}.\end{aligned}$$

- p-integral measure transforms as (same as Fujikawa chiral anomaly computation)

$$\begin{aligned}\ln \det \frac{\delta Q'(x)}{\delta Q(y)} &= \ln \det \begin{pmatrix} f(g)^{-1}\delta(x-y) & 0 \\ 0 & f(g)\delta(x-y) \end{pmatrix} = \\ \ln \det \begin{pmatrix} f(g)^{-1} & 0 \\ 0 & f(g) \end{pmatrix} \delta(x-y) &= \ln \det \delta(x-y),\end{aligned}$$

$$Q \equiv (\vec{A}, \vec{E})$$
