

The role of the tetraquark at nonzero temperature

Achim Heinz

in collaboration with S. Strüber, F. Giacosa, D. H. Rischke

3rd February 2010

Outline

- 1 Introduction
 - Why do we need tetraquarks?
 - What is a tetraquark?
- 2 Our model
 - Our potential
 - Untwiddle the masses
 - Nonzero T model
- 3 Results
 - Our potential
 - Order of phase transition
 - T dependence
- 4 Conclusion and outlook

Why do we need tetraquarks?

a simple idea to create matter is to combine a quark and an antiquark (quarkonium) to a meson

Why do we need tetraquarks?

a simple idea to create matter is to combine a quark and an antiquark (quarkonium) to a meson

- below 1.8 GeV we have more resonances than expected from an quarkonium picture
- lattice finds for scalar mesons higher masses
 $M_{u\bar{d}} = 1.4 - 1.5 \text{ GeV}$
- scalar quarkonia are p-wave states ($L = S = 1$), thus expected to be heavier than 1 GeV as tensor and axial-vector mesons
- mass degeneracy of $a_0(980)$ and $f_0(980)$

Why do we need tetraquarks?

a simple idea to create matter is to combine a quark and an antiquark (quarkonium) to a meson

- below 1.8 GeV we have more resonances than expected from an quarkonium picture
- lattice finds for scalar mesons higher masses
 $M_{u\bar{d}} = 1.4 - 1.5 \text{ GeV}$
- scalar quarkonia are p-wave states ($L = S = 1$), thus expected to be heavier than 1 GeV as tensor and axial-vector mesons
- mass degeneracy of $a_0(980)$ and $f_0(980)$

a possible solution to all these problems is to interpret the light scalars as tetraquark states

What is a tetraquark?

a tetraquark is a four quark state

What is a tetraquark?

a tetraquark is a four quark state

combine two quarks to a coloured diquark and couple two diquarks
two a colourneutral particle

$$|qq\rangle = |\text{Space: } L = 0\rangle |\text{Spin: } (\uparrow\downarrow - \downarrow\uparrow)\rangle |f: (ud - du)\rangle |c: (RB - BR)\rangle$$

$$|qq\rangle = \rho_k = \sqrt{\frac{1}{2}} \epsilon_{ijk} q_i^\dagger (C\gamma^5) q_j$$

$$\begin{array}{lll} u \Leftrightarrow [\bar{d}, \bar{s}] & d \Leftrightarrow [\bar{s}, \bar{u}] & s \Leftrightarrow [\bar{u}, \bar{d}] \\ \bar{u} \Leftrightarrow [d, s] & \bar{d} \Leftrightarrow [s, u] & \bar{s} \Leftrightarrow [u, d] \end{array}$$

out of this correspondency, you can build up a tetraquark nonet

What is a tetraquark?

- tetraquark picture generates many resonances
- $f_0(600)$ is an s-wave state, thus it can be lighter than 1 GeV
- mass degeneracy of $a_0(980)$ and $f_0(980)$ can be explained with constituent quarks

Our potential

the model we use is the $SU(2)_r \times SU(2)_l$ limit of the $SU(3)_r \times SU(3)_l$ case

F. Giacosa, **Phys.Rev.D75:054007 (2007)**

A. Heinz, S. Strüber, F. Giacosa, and D. H. Rischke,
Phys.Rev.D79:037502 (2009)

Our potential

the model we use is the $SU(2)_r \times SU(2)_l$ limit of the $SU(3)_r \times SU(3)_l$ case

F. Giacosa, **Phys.Rev.D75:054007 (2007)**

A. Heinz, S. Strüber, F. Giacosa, and D. H. Rischke,
Phys.Rev.D79:037502 (2009)

linear sigma model + tetraquark

$$V = \frac{\lambda}{4} (\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi$$

Our potential

the model we use is the $SU(2)_r \times SU(2)_l$ limit of the $SU(3)_r \times SU(3)_l$ case

F. Giacosa, **Phys.Rev.D75:054007 (2007)**

A. Heinz, S. Strüber, F. Giacosa, and D. H. Rischke,
Phys.Rev.D79:037502 (2009)

linear sigma model + tetraquark

$$V = \frac{\lambda}{4}(\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi + \frac{1}{2}M_\chi^2\chi^2 - g\chi(\vec{\pi}^2 + \varphi^2)$$

tetraquark: $\chi = \rho^\dagger \rho$

diquark: $\rho = \sqrt{\frac{1}{2}}\epsilon_{ij}q_i^\dagger(C\gamma^5)q_j$

for $SU(2)$ each diquark ρ is invariant under chiral transformation

Untwiddle the masses

$$V = \frac{\lambda}{4}(\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi + \frac{1}{2}M_\chi^2\chi^2 - g\chi(\vec{\pi}^2 + \varphi^2)$$

$$\varphi_0 = \frac{F}{\sqrt{1-(2g)/(\lambda M_\chi^2)}} + \frac{\epsilon}{2\lambda F^2} + \dots$$

quark condensate

$$\chi_0 = \frac{g}{M_\chi^2}\varphi_0^2$$

tetraquark condensate

Untwiddle the masses

$$V = \frac{\lambda}{4}(\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi + \frac{1}{2}M_\chi^2\chi^2 - g\chi(\vec{\pi}^2 + \varphi^2)$$

$$\varphi_0 = \frac{F}{\sqrt{1-(2g)/(\lambda M_\chi^2)}} + \frac{\epsilon}{2\lambda F^2} + \dots \quad \text{quark condensate}$$

$$\chi_0 = \frac{g}{M_\chi^2}\varphi_0^2 \quad \text{tetraquark condensate}$$

expanding the potential around the minimum:

$$V = \frac{1}{2}(\chi, \varphi) \begin{pmatrix} M_\chi^2 & -2g\varphi_0 \\ -2g\varphi_0 & M_\varphi^2 \end{pmatrix} \begin{pmatrix} \chi \\ \varphi \end{pmatrix} + \frac{1}{2}M_\pi^2\vec{\pi}^2 + \dots$$

$$\text{where } M_\varphi^2 = \varphi_0^2 \left(3\lambda - \frac{2g^2}{M_\chi^2} \right) - \lambda F^2 \quad \text{and} \quad M_\pi^2 = \frac{\epsilon}{\varphi_0}$$

non diagonal mass matrix

$$-2g\varphi_0\varphi\chi$$

since the mass matrix is not diagonal we have to diagonalize the potential

Untwiddle the masses

H and S chosen to diagonalize the potential

$$\begin{pmatrix} H \\ S \end{pmatrix} = \begin{pmatrix} \cos \theta_0 & \sin \theta_0 \\ -\sin \theta_0 & \cos \theta_0 \end{pmatrix} \begin{pmatrix} \chi \\ \varphi \end{pmatrix} = B \begin{pmatrix} \chi \\ \varphi \end{pmatrix}$$

Untwiddle the masses

H and S chosen to diagonalize the potential

$$\begin{pmatrix} H \\ S \end{pmatrix} = \begin{pmatrix} \cos \theta_0 & \sin \theta_0 \\ -\sin \theta_0 & \cos \theta_0 \end{pmatrix} \begin{pmatrix} \chi \\ \varphi \end{pmatrix} = B \begin{pmatrix} \chi \\ \varphi \end{pmatrix} \equiv \begin{pmatrix} f_0(600) \\ f_0(1370) \end{pmatrix}$$

Untwiddle the masses

H and S chosen to diagonalize the potential

$$\begin{pmatrix} H \\ S \end{pmatrix} = \begin{pmatrix} \cos \theta_0 & \sin \theta_0 \\ -\sin \theta_0 & \cos \theta_0 \end{pmatrix} \begin{pmatrix} \chi \\ \varphi \end{pmatrix} = B \begin{pmatrix} \chi \\ \varphi \end{pmatrix} \equiv \begin{pmatrix} f_0(600) \\ f_0(1370) \end{pmatrix}$$

$$V = \frac{1}{2}(\chi, \varphi) B^t B \begin{pmatrix} M_\chi^2 & -2g\varphi_0 \\ -2g\varphi_0 & M_\varphi^2 \end{pmatrix} B^t B \begin{pmatrix} \chi \\ \varphi \end{pmatrix} + \dots$$

$$= \frac{1}{2}(H, S) \begin{pmatrix} M_H^2 & 0 \\ 0 & M_S^2 \end{pmatrix} \begin{pmatrix} H \\ S \end{pmatrix} + \dots$$

$$\theta_0 = \frac{1}{2} \arctan \frac{4g\varphi_0}{M_\varphi^2 - M_\chi^2}, \quad -\frac{\pi}{4} < \theta_0 < \frac{\pi}{4}$$

$$M_H^2 = M_\chi^2 \cos^2 \theta_0 + M_\varphi^2 \sin^2 \theta_0 - 2g\varphi_0 \sin(2\theta_0)$$

$$M_S^2 = M_\varphi^2 \cos^2 \theta_0 + M_\chi^2 \sin^2 \theta_0 + 2g\varphi_0 \sin(2\theta_0)$$

$$(M_S^2 - M_H^2)^2 = (M_\varphi^2 - M_\chi^2)^2 + (4g\varphi_0)^2 \rightarrow |M_S^2 - M_H^2| \geq 4g\varphi_0$$

Nonzero T model

we employ the CJT-formalism in the Hartree-Fock approximation to calculate the T dependency of our masses, condensates and mixing angle

Nonzero T model

we employ the CJT-formalism in the Hartree-Fock approximation to calculate the T dependency of our masses, condensates and mixing angle

masses, condensates and mixing angle become T dependent

$$\begin{array}{lll} M_H \rightarrow M_H(T) & M_S \rightarrow M_S(T) & M_\pi \rightarrow M_\pi(T) \\ \varphi_0 \rightarrow \varphi(T) & \chi_0 \rightarrow \chi(T) & \theta_0 \rightarrow \theta(T) \end{array}$$

$$\begin{array}{lll} M_H(0) = M_H & M_S(0) = M_S & M_\pi(0) = M_\pi \\ \varphi(0) = \varphi_0 & \chi(0) = \chi_0 & \theta(0) = \theta_0 \end{array}$$

Range of the parameters

our potential

$$V = \frac{\lambda}{4}(\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi + \frac{1}{2}M_\chi^2\chi^2 - g\chi(\vec{\pi}^2 + \varphi^2)$$

Range of the parameters

our potential

$$V = \frac{\lambda}{4}(\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi + \frac{1}{2}M_\chi^2\chi^2 - g\chi(\vec{\pi}^2 + \varphi^2)$$

two known values

$$M_\pi = 0.139 \text{ GeV}$$

$$\varphi_0 = f_\pi = 0.0924 \text{ GeV}$$

Range of the parameters

our potential

$$V = \frac{\lambda}{4}(\vec{\pi}^2 + \varphi^2 - F^2)^2 - \epsilon\varphi + \frac{1}{2}M_\chi^2\chi^2 - g\chi(\vec{\pi}^2 + \varphi^2)$$

two known values

$$M_\pi = 0.139 \text{ GeV}$$

$$\varphi_0 = f_\pi = 0.0924 \text{ GeV}$$

three approximately known values

$$M_H \approx 0.4 \text{ GeV}$$

$$f_0(600) = 0.4 \text{ GeV} - 1.2 \text{ GeV}$$

$$M_S \approx 1.2 \text{ GeV}$$

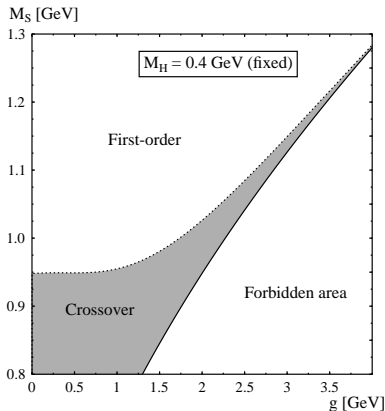

$$f_0(1370) = 1.2 \text{ GeV} - 1.5 \text{ GeV}$$

g should be of the order of a few GeV

to manage these uncertainties we study variation of g , M_S and M_H

A. Heinz, S. Strüber, F. Giacosa, and D. H. Rischke, **Phys.Rev.D79:037502 (2009)**

$M_H = 0.4 \text{ GeV}$ fixed, g and M_S vary

- forbidden area arises from $|M_S^2 - M_H^2| \geq 4g\varphi_0$
- between first order and crossover region we find a second order phase transition
- $g \rightarrow 0$:
 χ and φ decouple
 $H \rightarrow \chi, S \rightarrow \varphi$
 $M_S > 0.948 \text{ GeV}$:
 first order phase transition
 $M_S < 0.948 \text{ GeV}$:
 crossover phase transition

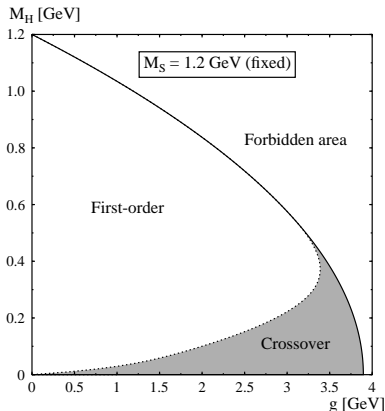

T_c behaviour

increasing of g :

- mixing increases
- T_c decreases
- first order softens
- crossover is obtained for large g

$M_S = 1.2 \text{ GeV}$ fixed, g and M_H vary

- forbidden area arises from $|M_S^2 - M_H^2| \geq 4g\varphi_0$
- between first order and crossover region we find a second order phase transition
- $g \rightarrow 0$:
 χ and φ decouple
 $H \rightarrow \chi, S \rightarrow \varphi$
 we get first order phase transition
- to get a crossover for a large M_S we need a large gap between M_S and M_H

Condensate

$M_H = 0.4 \text{ GeV}$, $M_S = 1.2 \text{ GeV}$ and $g = 3.4 \text{ GeV}$

- crossover phase transition at $T_c \approx 170 \text{ MeV}$
- $T < T_c$:
 $\chi(T)$ goes like $\frac{g}{M_\chi^2} \phi(T)^2$
- $T > T_c$:
 $\chi(T)$ increases

Masses and mixing angle

$$M_H = 0.4 \text{ GeV}, M_S = 1.2 \text{ GeV} \text{ and } g = 3.4 \text{ GeV}$$

- predominantly $M_S(T)$ consists of quarkonium
- predominantly $M_H(T)$ consists of tetraquark
- mixing angle $\theta(T)$ increases till $T_s = 155 \text{ MeV}$, then sign becomes negative
 T_s defined as $\theta(T_s) = \frac{\pi}{4}$
- at T_s both masses behave discontinuously and the states interchange their roles
- for large T the mixing goes to zero and everything behaves like in the linear sigma model

Conclusion and outlook

- a T dependent model including a tetraquark state
- order of phase transition changes with coupling g ;
if coupling g and mixing is large enough we also obtain a crossover phase transition for a mass of the chiral partner above 1 GeV
- mixing increases with T and at a temperature T_s a role interchange takes place

- include glueball states and vectormesons

Thank you
for your attention
